\text{USL}&=\text{required by customer/board comitee}\\
\text{UCL}_S&=\overline{S}+3\frac{\overline{S}}{c_4(n_i)}\sqrt{1-c_4^2(n_i)}=\overline{S}+3\frac{\overline{S}}{h(n_i)}\\
\text{CL}_S&=\overline{S}\\
T&=\text{target required by customer/board comitee}\\
\text{LCL}_S&=\overline{S}-3\frac{\overline{S}}{c_4(n_i)}\sqrt{1-c_4^2(n_i)}=\overline{S}-3\frac{\overline{S}}{h(n_i)}\\
\text{LSL}&=\text{required by customer/board comitee}
\end{aligned}} \tag{16.7.790}$$

where by definition:

$$\boxed{h(n_i)=\frac{c_4(n_i)}{\sqrt{1-c_4^2(n_i)}}} \tag{16.7.791}$$

That can be also sometimes be found in some books written as:

$$\boxed{\begin{aligned}
\text{USL}&=\text{required by customer/board comitee}\\
\text{UCL}_S&=\overline{S}\left(1+\frac{3}{h_i}\right)=\overline{S}B_4(n_i)\\
\text{CL}_S&=\overline{S}\\
T&=\text{target required by customer/board comitee}\\
\text{LCL}_S&=\overline{S}\left(1-\frac{3}{h_i}\right)=\overline{S}B_3(n_i)\\
\text{LSL}&=\text{required by customer/board comitee}
\end{aligned}} \tag{16.7.792}$$

with by definition the following unbiasing constants:

$$
\boxed{\begin{aligned}
B_4(n_i) &= 1+\frac{3}{h(n_i)} = 1+\frac{3\sqrt{1-c_4^2(n_i)}}{c_4(n_i)} \\
B_3(n_i) &= 1-\frac{3}{h(n_i)} = 1-\frac{3\sqrt{1-c_4^2(n_i)}}{c_4(n_i)}
\end{aligned}} \tag{16.7.793}
$$

The unbiasing constants c_4, B_3, B_4 (all dependent of n_i) can obviously be found in many tables in various books or softwares, but once again they can be easily computed using a simple spreadsheet software like Microsoft® Excel® as proved earlier above.

As companion example let us once again consider the following example of 25 samples (that we will identify by the variable k) of 6 individuals each (that we will identify by the variable $n_i = n$) taken from a continuous manufacturing process (without machine recalibration or without machine change!):

	A	B	C	D	E	F	G
5		Sample 1	Sample 2	Sample 3	Sample 4	Sample 5	Sample 6
6	Day 1	9.994	10.020	9.973	10.009	9.969	9.954
7	Day 2	9.972	9.964	9.943	9.971	10.026	10.018
8	Day 3	9.979	10.021	9.941	10.070	10.016	10.071
9	Day 4	10.066	10.080	9.951	9.996	10.034	10.042
10	Day 5	10.014	9.979	9.945	9.940	9.942	9.942
11	Day 6	9.950	10.006	9.972	10.039	10.002	9.962
12	Day 7	9.914	10.032	10.036	10.025	10.011	9.994
13	Day 8	9.975	9.996	10.037	10.150	10.000	9.974
14	Day 9	10.006	10.075	9.997	9.978	9.993	9.956
15	Day 10	10.084	9.962	10.006	10.036	9.991	9.976
16	Day 11	9.944	10.064	9.962	10.014	9.967	9.959
17	Day 12	10.007	9.982	9.975	10.054	9.985	9.911
18	Day 13	10.007	10.028	10.039	9.975	10.032	9.986
19	Day 14	9.984	10.063	9.982	9.991	9.968	10.058
20	Day 15	10.032	10.049	9.966	10.068	10.005	10.028
21	Day 16	9.976	9.917	9.908	9.991	10.018	9.998
22	Day 17	9.982	9.896	9.961	9.961	9.969	9.935
23	Day 18	10.017	10.004	10.003	9.955	10.020	9.969
24	Day 19	9.986	10.050	10.038	9.981	9.960	9.912
25	Day 20	9.988	9.984	9.950	9.975	9.953	10.058
26	Day 21	10.066	9.984	9.964	9.978	10.042	10.055
27	Day 22	9.956	10.018	9.989	10.000	10.015	10.015
28	Day 23	10.061	9.944	9.990	9.983	9.995	10.003
29	Day 24	9.905	9.905	9.987	10.058	9.916	9.978
30	Day 25	9.977	9.995	9.920	9.934	9.916	10.072

where every day we took a sample of 6 individuals of all manufactured items produced the same day.

Once again using our spreadsheet software here are the calculations we get in the simple case where all sample still have the same size (calculations based on the previous list of data given just earlier above):

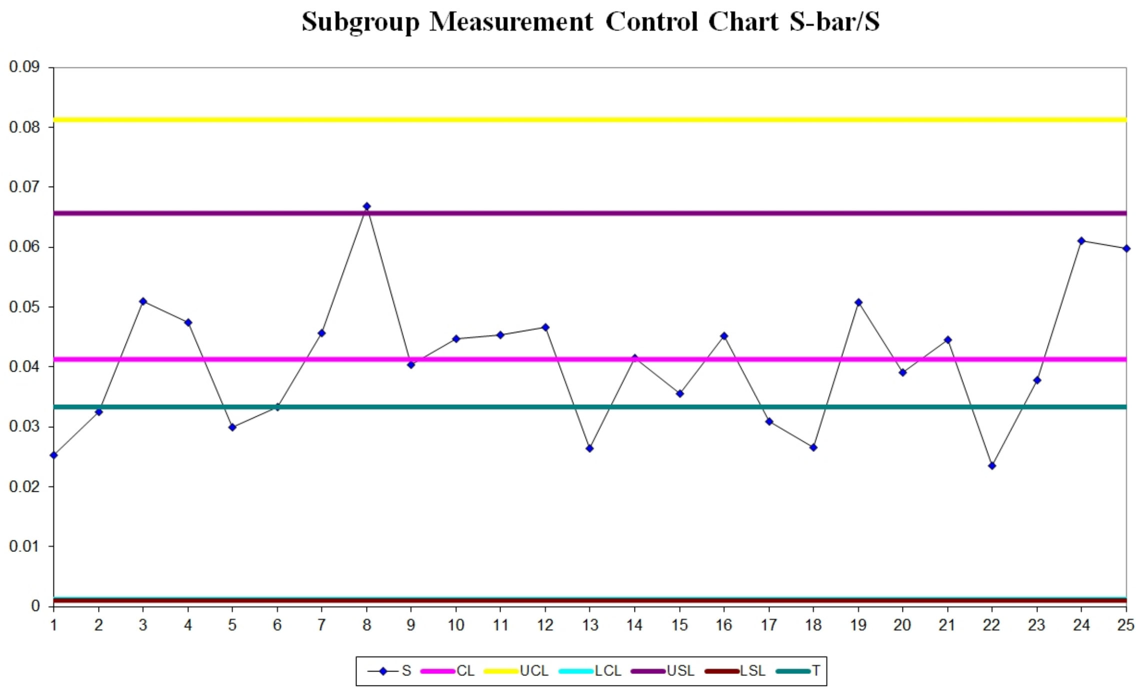
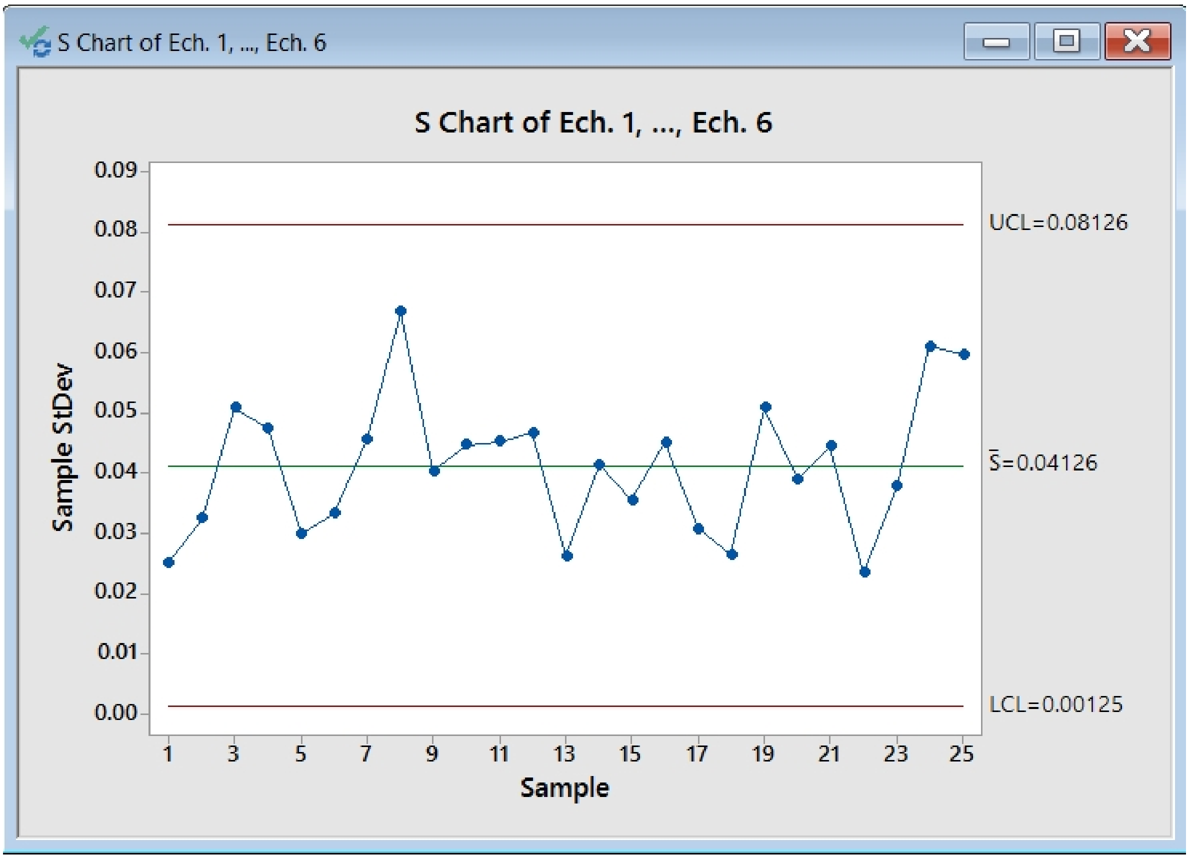
and the corresponding chart still with the same spreadsheet software:



where we took as example for limits imposed by the customer/board committee:

$$\begin{aligned}\text{USL}&=0.0\bar{3}B_4(n_i)=0.0\bar{3}B_4(6)=0.0657\\ T&=0.0\bar{3}\\ \text{LSL}&=0.0\bar{3}B_3(n_i)=0.0\bar{3}B_3(6)=0.001\end{aligned} \quad (16.7.794)$$

With Minitab 17.1.3 this gives for people that don't trust our calculations made with Microsoft® Excel® (we can also do such a chart with `R` but the plot quality output is not acceptable in most corporations):



Let us notice that this control chart would according to the WECO rules have 0 points beyond the $\pm 3\sigma$ (we indicate that for reasons of comparison with the previous control chart and the next one). It is therefore more sensitive to changes than the control chart. Also notice that the UCL and LCL limits are wider than the imposed USL and LSL.

For recall, the major problem with this control chart is that it is correct if and only if the data are Normally distributed and that Shewhart limits suppose that S is symmetric and here in fact it is note case (if we took probabilistic limits). Therefore, the quality manager then combine with the average control chart another optional control which we will introduce now.

16.7.6.4.5 $\overline{X}-S$ Subgroups measurement control chart

During our study of the control chart with averages with fixed limits based on the standard deviation of the mean (standard error), we have clearly shown that it suffered from the handicap that σ_X is too approximative in practice (because n_i is often too small).

Therefore, a workaround to this is to use the results obtained from the study of the previous control chart.

Pros:

- Corrects the problem of the control chart for averages with standard error when the number of individuals per sample is too small.
- Represents well the change of level in the average of data (central tendency).

Cons:

- The mathematical proof of the origin of the control chart limits is quite difficult for undergraduates (see page 8980).
- This control chart only works if and only if the data are identically distributed and are Normally distributed!
- Moreover, since the limits are based on the estimator of the standard deviation it would require however n_i that in the idea should not be below the value of 10 ...

First let us recall that for the average control chart with standard error limits we get:

$$\begin{aligned}\text{USL}&=\text{required by customer/board comitee}\\ \text{UCL}_{\text{SE}}&=\overline{\overline{X}}+3\sigma_{\overline{X}}=\overline{\overline{X}}+3\frac{\sigma_X}{\sqrt{n_i}}\\ \text{CL}_{\text{SE}}&=\text{E}(\overline{X})=\overline{\overline{X}}\\ T_{\text{SE}}&=\text{target required by customer/board comitee}\\ \text{LCL}_{\text{SE}}&=\overline{\overline{X}}-3\sigma_{\overline{X}}=\overline{\overline{X}}-3\frac{\sigma_X}{\sqrt{n_i}}\\ \text{LSL}&=\text{required by customer/board comitee}\end{aligned} \tag{16.7.795}$$

and we have proved earlier above:

$$\bar{S}=\sigma_X c_4(n_i) \tag{16.7.796}$$

We have therefore:

$$\boxed{\begin{aligned}\text{USL} &= \text{required by customer/board comitee}\\ \text{UCL}_{\overline{X}(S)} &= \overline{\overline{X}}+3\frac{\sigma_X}{\sqrt{n_i}}=\overline{\overline{X}}+3\frac{\overline{S}}{c_4(n_i)\sqrt{n_i}}\\ \text{CL}_{\overline{X}(S)} &= \overline{\overline{X}}\\ T_{\overline{X}(S)} &= \text{target required by customer/board comitee}\\ \text{LCL}_{\overline{X}(S)} &= \overline{\overline{X}}-3\frac{\sigma_X}{\sqrt{n_i}}=\overline{\overline{X}}-3\frac{\overline{S}}{c_4(n_i)\sqrt{n_i}}\\ \text{LSL} &= \text{required by customer/board comitee}\end{aligned}} \tag{16.7.797}$$

and that we sometimes find in the literature written as:

$$\boxed{\begin{aligned}\text{USL} &= \text{required by customer/board comitee}\\ \text{UCL}_{\overline{X}(S)} &= \overline{\overline{X}}+3\frac{\overline{S}}{c_4(n_i)\sqrt{n_i}}=\overline{\overline{X}}+A_3(n_i)\overline{S}\\ \text{CL}_{\overline{X}(S)} &= \overline{\overline{X}}\\ T_{\overline{X}(S)} &= \text{target required by customer/board comitee}\\ \text{LCL}_{\overline{X}(S)} &= \overline{\overline{X}}-3\frac{\overline{S}}{c_4(n_i)\sqrt{n_i}}=\overline{\overline{X}}-A_3(n_i)\overline{S}\\ \text{LSL} &= \text{required by customer/board comitee}\end{aligned}} \tag{16.7.798}$$

with the unbiasing constant:

$$\boxed{A_3(n_i)=\frac{3}{c_4(n_i)\sqrt{n_i}}} \tag{16.7.799}$$

Remark

The choice of the estimator for the $\bar{X}$ control chart when the process distribution is non-normal depends on the situation at hand. When the limits based on normality are applied, the best estimator is the estimator based on $\tilde{S}$ (pooled sample standard deviation) since the resulting charts perform the best both under normality and under non-normality according to [483].

Notice then that we can calculate the probabilities of non-compliance by excess or defect of subgroups using the fact that $\overline{X}$ follows a Normal distribution of parameters:

$$\mathcal{N}(\mu,\sigma)\cong\mathcal{N}\left(\overline{\overline{X}},\frac{\overline{S}}{c_4(n_i)\sqrt{n}}\right) \tag{16.7.800}$$

As companion example let us once again consider the following example of 25 samples (that we will identify by the variable k) of 6 individuals each (that we will identify by the variable $n_i=n$) taken from a continuous manufacturing process (without machine recalibration or without machine change!):

	A	B	C	D	E	F	G
4		Sample 1	Sample 2	Sample 3	Sample 4	Sample 5	Sample 6
5	Day 1	9.9943	10.0196	9.9732	10.0088	9.9685	9.9544

28	Day 24	9.9054	9.9049	9.9870	10.0580	9.9156	9.9782
29	Day 25	9.9768	9.9954	9.9196	9.9341	9.9162	10.0721

where every day we took a sample of 6 individuals of all manufactured items produced the same day.

We can calculate, or find in the tables that:

$$c_4(n_i)=c_4(6)=0.9515 \qquad A_3(n_i)=A_3(6)=0.630 \tag{16.7.801}$$

We then have the following table:

	I	J	K	L	M	N	O	P	Q
1	**c4**	0.952							
2	**a3**	1.287

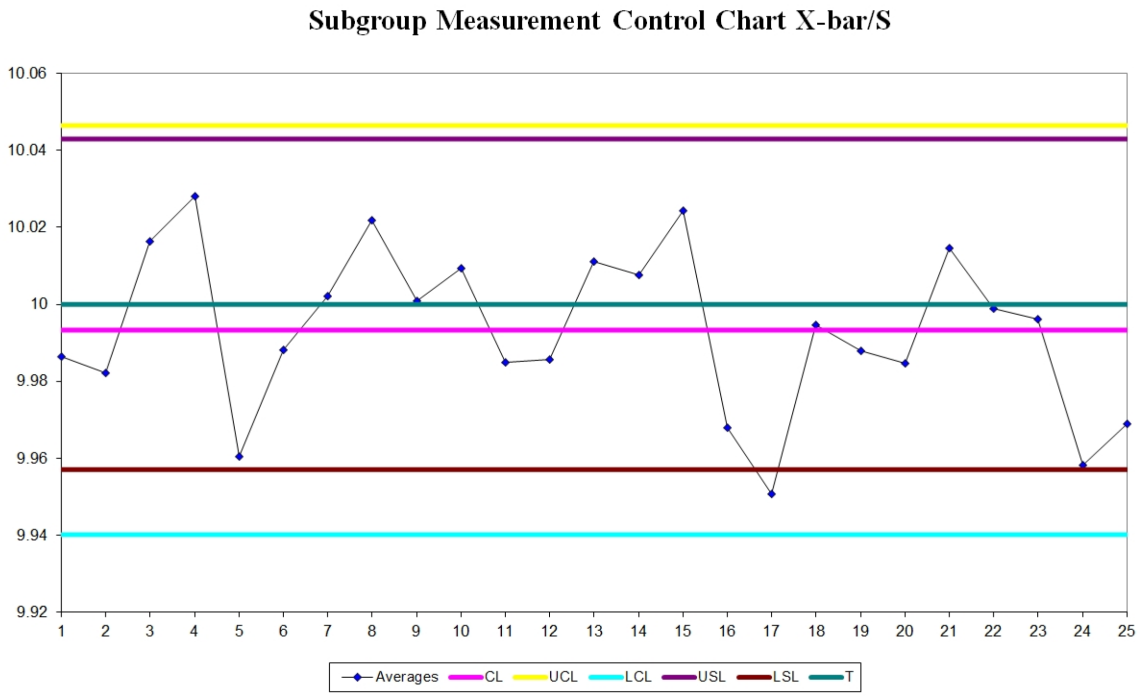
29	25	=MOYENNE(B29:G29)	=MOYENNE($J$5:$J$29)	=ECARTYPE(B29:G29)	=$K29+MOYENNE($L$5:$L$29)*$J$2	=$K29-MOYENNE($L$5:$L$29)*$J$2	=10+0.1*$J$2/3	=10-0.1*$J$2/3	10

and the corresponding chart still with the same spreadsheet software:



where we took as example for limits imposed by the customer/board committee:

$$\begin{aligned}\text{USL}&=10+0.0\bar{3}A_3(n_i)=10+0.0\bar{3}A_3(6)=10.021\\ T_{\overline{X}(S)}&=10\\ \text{LSL}&=10-0.0\bar{3}A_3(n_i)=1-+0.0\bar{3}A_3(6)=9.979\end{aligned} \tag{16.7.802}$$

With Minitab 17.1.3 this gives for people that don't trust our calculations made with Microsoft® Excel® (we can also do such a chart with `R` but the plot quality output is not acceptable in most corporations):

Let us notice that this control chart would according to the WECO rules have 1 point beyond the $\pm 3\sigma$ (we indicate that for reasons of comparison with the previous control chart and the next one). It is therefore more sensitive to changes than the control chart. Also notice that the UCL and LCL limits are wider than the imposed USL and LSL.

For recall, the major problem with this control chart is that it is correct if and only if the data are Normally distributed and that Shewhart limits suppose that S is symmetric and here in fact it is note case (if we took probabilistic limits). Therefore, the quality manager then combine with the average control chart another optional control chart which we will introduce now.

16.7.6.4.6 $\overline{X} - S_P$ Subgroups measurement control chart with pooled variance

As we have seen it the standard error based control chart suppose all measurements as whole (that means we suppose that each subgroup has the same mean). This is in fact not really accurate as every group is supposed as being independent and has to be compared with the others. So identically at the T-test or ANOVA for independent groups we use the "pooled variance" as overall indicator and as a generalization of the standard error (the pooled estimate the variance of several different populations when the mean may be different[37], but one may assume that the variance of each population is for recall the same!!!).

Therefore the pooled variance control chart is based on the following relation proved in the section Statistics during our study of ANOVA (see page 1001):

---

[37] Therefore it increase the power of a corresponding test

$$\mathrm{V}_R = \frac{\sum\limits_{ij}(x_{ij}-\bar{x}_i)^2}{\sum\limits_i (n_i - 1)} \tag{16.7.803}$$

or in a more common obvious notation for control charts:

$$\sigma_R = \sqrt{\frac{\sum\limits_{ij}(x_{ij}-\bar{x}_i)^2}{\sum\limits_i (n_i - 1)}} \tag{16.7.804}$$

But as above... we can use if we want the unbiasing constant c_4 of the variance as it applies similarly at the difference that (the notation is a little bit sad):

$$c_4(n) = c_4\left(1+\sum_i (n_i - 1)\right) \tag{16.7.805}$$

where the $1+$ is here because in the case where $n_i = 2$ (minimum case for the calculation of a variance) we would have without it $c_4(1)$ and that latter is not defined, that's why!

But in fact it's quite useless in the situation of the pooled variance. Normally unbiasing constant c_4 is for small samples... but when the parameter of the constant is $\sum_i (n_i - 1)$ then:

$$1+\sum_i (n_i - 1) \gg n_i \tag{16.7.806}$$

and it follows that:

$$c_4\left(1+\sum_i (n_i - 1)\right) \rightarrow 1 \tag{16.7.807}$$

To convinced yourself you can see below the calculated values of $c_4(n)$ using the relation constant given earlier above. As requested by some of my students here are some tabulated values:

n	c_4
1	$*$
2	0.797885
3	0.886227
4	0.921318
5	0.939986
10	0.972659
15	0.982316
20	0.986934
30	0.991418
40	0.993611
50	0.994911
70	0.996383
90	0.997195

Table 16.59: **Unbiasing constant c_4**

But as most of time the correction is smaller than the measurement precision... I let you therefore guess if it is very useful...

But we still can write (we like to write it by highlighting the fact that we are using the pooled variance so we avoid to use too much condensed notations!):

$$\boxed{\begin{aligned}\text{USL}&=\text{required by customer/board comitee}\\ \text{UCL}_{\overline{X}(S)}&=\overline{\overline{X}}+3\frac{\sigma_X}{\sqrt{n_i}}=\overline{\overline{X}}+3\frac{\sqrt{\frac{\sum_{ij}(x_{ij}-\bar{x}_i)^2}{\sum_i(n_i-1)}}}{c_4\left(1+\sum(n_i-1)\right)\sqrt{n_i}}\\ \text{CL}_{\overline{X}(S)}&=\overline{\overline{X}}\\ T_{\overline{X}(S)}&=\text{target required by customer/board comitee}\\ \text{LCL}_{\overline{X}(S)}&=\overline{\overline{X}}-3\frac{\sigma_X}{\sqrt{n_i}}=\overline{\overline{X}}-3\frac{\sqrt{\frac{\sum_{ij}(x_{ij}-\bar{x}_i)^2}{\sum_i(n_i-1)}}}{c_4\left(1+\sum(n_i-1)\right)\sqrt{n_i}}\\ \text{LSL}&=\text{required by customer/board comitee}\end{aligned}} \tag{16.7.808}$$

where we often write in practice:

$$\text{df}=c_4\left(1+\sum(n_i-1)\right) \tag{16.7.809}$$

As companion example let us consider the following example of 25 samples of 6 individuals each (that we will identify by the variable $n_i=n$) taken from a continuous manufacturing process (without machine recalibration or without machine change!):

	A	B	C	D	E	F	G
4		Sample 1	Sample 2	Sample 3	Sample 4	Sample 5	Sample 6
5	Day 1	9.9943	10.0196	9.9732	10.0088	9.9685	9.9544
6	Day 2	9.9721	9.9643	9.9426	9.9712	10.0259	10.0177

and let us focus on an example with the use of the unbiasing constant and always providing a detailed Microsoft® Excel® example and showing afterwards the corresponding Minitab plot!

So every day we took $n_i = 6$ individuals of all manufactured items produced the same day.

We can calculate, or find in the tables that:

$$c_4(1+\sum(n_i-1)) = c_4(126) = 0.9980 \qquad (16.7.810)$$

We then have the following table:

	I	J	K	L	M	N
1	**df**	126				
2	**c$_4$**	0.9980				
3						
4	**N°**	**Measurement Averages**	**CL**	**SSE**	**UCL**	**LCL**
5	1	9.9865	9.9933	0.0032	10.0458	9.9408

Let us notice that this control chart would according to the WECO rules have 0 point beyond the $\pm 3\sigma$ (we indicate that for reasons of comparison with the previous control chart and the next one).

For recall, the major problem with this control chart is that it is correct if and only if the data are Normally distributed!

16.7.6.4.7 $\overline{R}-R$ Subgroups measurement control chart

The range control chart is often associated with the average control chart. It aims to advantageously replace the standard deviation control chart $\overline{S}-S$ when data are not Normally distributed, because it's mathematical construction allows if desired to choose the underlying probability distribution! So we use this new control chart when $n_i \leq 10$ (the number of individuals per sample), while for the control chart for the standard deviation we must instead $n_i \geq 10$.

Pros:

- Completes well the average control chart and replaces well the control chart of the standard deviation when the number of samples is small.
- Represents well the variation within each sample of data (instantaneous dispersion) that we could detect.

Cons:

- The mathematical proof of the origin of the limits of controls is quite hard (see the section of Statistics for the detailed proof) and the determination of the corresponding unbiasing coefficients requires the use of Monte Carlo simulations (see section Numerical Methods page 6708).
- Another problem is that even if the probability distribution of sample size can be chosen, it is often given in specialized books only for the Normal distribution... (but softwares such as Minitab manage them).

The idea is to represent (due to the possible asymmetry of R it is impossible - nonsense - that the customer sets coherent USL and LSL or a target T as regards to the range, hence the fact that these parameters will this time not be listed or represented):

$$\begin{aligned}\text{UCL}_R &= \overline{R}+3\sigma_R\\ \text{CL}_R &= \text{E}(R)=\overline{R}\\ \text{LCL}_R &= \overline{R}-3\sigma_R\end{aligned} \tag{16.7.811}$$

and this time we will not use estimators of the standard deviation for the range as it does not converge fast enough. Therefore, we will use the results proved in the section Statistics during our study of range statistics (see section Statistics page 1203). We obtained for the estimator of the standard deviation with the unbiasing Hartley's constants:

$$\boxed{\sigma_R=\frac{d_3(n)\overline{R}}{d_2(n)}=\frac{d_3\overline{R}}{d_2}} \tag{16.7.812}$$

with:

$$\overline{R}=\frac{1}{k}\sum_{i=1}^{k}R_i \tag{16.7.813}$$

or depending of the softwares (the latter one is more logic if we think a little bit):

$$\overline{R}=\frac{1}{k-1}\sum_{i=1}^{k}R_i \tag{16.7.814}$$

Therefore:

$$\begin{aligned}\text{UCL}_R&=\overline{R}+3\sigma_R=\overline{R}+3\frac{d_3(n_i)\overline{R}}{d_2(n_i)}=\overline{R}\left(1+3\frac{d_3(n_i)\overline{R}}{d_2(n_i)}\right)\\ \text{CL}_R&=\text{E}(R)=\overline{R}\\ \text{LCL}_R&=\overline{R}-3\sigma_R=\overline{R}-3\frac{d_3(n_i)\overline{R}}{d_2(n_i)}=\overline{R}\left(1-3\frac{d_3(n_i)\overline{R}}{d_2(n_i)}\right)\end{aligned} \tag{16.7.815}$$

which is written traditionally:

$$\boxed{\begin{aligned}\text{UCL}_R&=\overline{R}+3\sigma_R=\overline{R}+3\frac{d_3(n_i)\overline{R}}{d_2(n_i)}=\overline{R}D_4(n_i)\\ \text{CL}_R&=\text{E}(R)=\overline{R}\\ \text{LCL}_R&=\overline{R}-3\sigma_R=\overline{R}-3\frac{d_3(n_i)\overline{R}}{d_2(n_i)}=\overline{R}D_3(n_i)\end{aligned}} \tag{16.7.816}$$

The unbiasing coefficients D_3, D_4 defined by:

$$\boxed{D_4=1+3\frac{d_3(n_i)\overline{R}}{d_2(n_i)}\qquad D_3=1-3\frac{d_3(n_i)\overline{R}}{d_2(n_i)}} \tag{16.7.817}$$

are available in the literature (or on Internet or also in the Help of Minitab) as a function of the n_i of the sample size and often (unfortunately) only for a Normal distribution (see the example in the section Statistics).

As companion example let us consider the following example of 25 samples (that we will identify by the variable k) of 6 individuals each (that we will identify by the variable $n_i=n$) taken from a continuous manufacturing process (without machine recalibration or without machine change!):

	A	B	C	D	E	F	G

which (is it necessary to recall it?) underestimates the number of error detections since the probability distribution of the range is in reality not symmetrical (hence the application of fixed Shewhart's control limits is not really suited...) and because almost all of the tables assume the data still Normally distributed as well.

Let us notice that this control chart would according to the WECO rules have 0 point beyond the $\pm 3\sigma$.

16.7.6.4.8 $\overline{X}-R$ Subgroups measurement control chart

During our study of the averages control chart averages with fixed limits based on the standard deviation of the mean and also of the $\overline{S}-S$ control chart, we have clearly discusses that it suffered from the handicap that σ_X is too approximate in practice (because n_i is often too small).

Therefore, a workaround is to use the results obtained from the study of the previous $\overline{R}-R$ control chart.

Pros:

- Corrects the problem of the control charge with for averages using the traditional standard deviation or also the unbiasing standard deviation approach when the number of individuals per sample is quite small.
- Represents well the change in the average level of data (central tendency).

Cons:

- The mathematical proof of the origin of the limits of controls is quite hard (see the section of Statistics at page 1203 for the detailed proof) and the determination of the corresponding unbiasing coefficients requires the use of Monte Carlo simulations (see section Numerical Methods page 6708).
- Another problem is that even if the probability distribution of sample size can be chosen, it is often given in specialized books only for the Normal distribution... (but softwares such as Minitab manage them).

Remark

This control chart is used a lot as part of the study of reproducibility and repeatability (R&R Studies). This is why it is found it often in statistical process control software as automatically processes control chart when launching a R&R analysis (typically what do Minitab).

Let us recall first that we had:

$$\begin{aligned}\text{USL} &= \text{required by customer/board comitee}\\ \text{UCL}_{\text{SE}} &= \overline{\overline{X}}+3\sigma_{\overline{X}}=\overline{\overline{X}}+3\frac{\sigma_X}{\sqrt{n_i}}\\ \text{CL}_{\text{SE}} &= \text{E}(\overline{X})=\overline{\overline{X}}\\ T_{\text{SE}} &= \text{target required by customer/board comitee}\\ \text{LCL}_{\text{SE}} &= \overline{\overline{X}}-3\sigma_{\overline{X}}=\overline{\overline{X}}-3\frac{\sigma_X}{\sqrt{n_i}}\\ \text{LSL} &= \text{required by customer/board comitee}\end{aligned} \tag{16.7.819}$$

and let us recall that we have proved in the section Statistics in the context of our study of range statistics (see page 1203) that:

$$\overline{R}=\sigma_X d_2 \tag{16.7.820}$$

It comes (it is impossible that the customer sets a limit for the USL, LSL or target T as regards the range as in general it is asymmetric, hence the fact that these parameters are this time not listed below):

$$\begin{aligned}\text{UCL}_{\overline{X}(R)} &= \overline{\overline{X}}+3\frac{\sigma_X}{\sqrt{n_i}}=\overline{\overline{X}}+3\frac{\overline{R}}{d_2(n_i)\sqrt{n_i}}\\ \text{CL}_{\overline{X}(R)} &= \text{E}(\overline{X})=\overline{\overline{X}}\\ \text{LCL}_{\overline{X}(R)} &= \overline{\overline{X}}-3\frac{\sigma_X}{\sqrt{n_i}}=\overline{\overline{X}}-3\frac{\overline{R}}{d_2(n_i)\sqrt{n_i}}\end{aligned} \tag{16.7.821}$$

still with:

$$\overline{R}=\frac{1}{k}\sum_{i=1}^{k}R_i \tag{16.7.822}$$

and the whole is traditionally written in the field:

$$\begin{aligned}\text{UCL}_{\overline{X}(R)} &= \overline{\overline{X}}+3\frac{\overline{R}}{d_2(n_i)\sqrt{n_i}}=\overline{\overline{X}}+A_2(n_i)\overline{R}\\ \text{CL}_{\overline{X}(R)} &= \text{E}(\overline{X})=\overline{\overline{X}}\\ \text{LCL}_{\overline{X}(R)} & \overline{\overline{X}}-3\frac{\overline{R}}{d_2(n_i)\sqrt{n_i}}=\overline{\overline{X}}-A_2(n_i)\overline{R}\end{aligned} \tag{16.7.823}$$

Notice that we can then calculate the probabilities of non-compliance by excess or defect of the subgroups by using the fact that $\overline{X}$ follows a Normal distribution of parameters:

$$\mathcal{N}(\overline{X},\sigma_{\overline{X}})\cong\mathcal{N}\left(\overline{\overline{X}},\frac{\overline{R}}{d_2(n_i)\sqrt{n_i}}\right) \tag{16.7.824}$$

As companion example let us consider the following example of 25 samples (that we will identify by the variable k) of 6 individuals each (that we will identify by the variable $n_i=n$) taken from a continuous manufacturing process (without machine recalibration or without machine change!):

	A	B	C	D	E	F	G

which (is it necessary to recall it?) underestimates the number of error detections since the probability distribution of the range is in reality not symmetrical (hence the application of fixed Shewhart's control limits is not really suited ...) and because almost all of the tables assume the data still Normally distributed as well.

Let us notice that this control chart would according to the WECO rules have 0 point beyond the $\pm 3\sigma$.

Finally for the people interested here are some data that may perhaps be useful to some people:

16.7.6.5 Autocorrelated Measurement Control Charts (time weighted control charts)

The family of autocorrelated control charts is defined by the fact that either the points on the chart or the control limits are calculated based on a number of the foregoing points.

These control chart have the advantage of requiring less data than others and to exacerbate the problem of deviation and therefore detect anomalies faster.

The WECO rules do not apply to autocorrelated control chart. If a point is outside the calculated limits the process requires an immediate corrective action.

16.7.6.5.1 $\mathrm{I}-\mathrm{MR}/\overline{X}$ Individual moving range measurement control chart

In prototyping phase, we can not put in place the concept of sampling. In addition, the measurement short term control chart on the mean with standard deviation does not gives the possibility to make statistical inference, because the distribution law is supposed unknown simply because the process is unstable.

An intermediate solution is to consider then that the process is stable (assumption of Normality of the data) and calculate the limits from a minimum number of individuals that it is possible to have to make a statistic. That is to say: two!

This situation is then well suited for prototyping phases or in the case of processes/methods with slow frequencies for which the measurements (pieces)/controls are very expensive.

Pros:

- Complete the first control charts (measurement on subgroups) that we saw at the beginning for situations where it is difficult to have a large number of individuals by sample for reasons of cost or time.
- This control chart is sometimes regarded as the Swiss Army knife of quality control ... and is increasingly used because it is the policy of the "Just in Time" (JIT) production for small series (for the decrease of costs).

Cons:

- The mathematical proof of the origin of the control limits is quite difficult (see the section Statistics at page page 1203 for detailed proof) and the determination of the coefficients requires the use of Monte Carlo simulation (see section Numerical Methods page 6708)).
- Another problem is that although the probability distribution of the range can be chosen, it is often given in specialized books only for the Normal distribution (but most advanced softwares manage various distribution laws).

As workaround of the problem of an acceptable estimate of the standard deviation, the idea is to consider two successive measurements x_{i-1},x_i as the random variables of a rank statistics of which we calculate the range in absolute terms:

$$\text{MR}_i=R_i=|x_i-x_{i-1}|=\max(x_{i-1},x_i)-\min(x_{i-1},x_i) \quad (16.7.826)$$

where MR stands for "Moving Range" (the control chart is sometimes named "MR(2) control chart"). And then we have:

$$\overline{\text{MR}}=\overline{R}=\frac{1}{n-1}\sum_{i=1}^{n}|x_i-x_{i-1}| \quad (16.7.827)$$

since we have necessarily $n-1$ moving ranges.

Then we take back the definitions of the control chart by measurement for the mean with short term standard deviation:

$$\begin{aligned}\text{USL}&=\text{required by customer/board comitee}\\ \text{UCL}_{\overline{X}}&=\overline{\overline{X}}+3\sigma_X\\ \text{CL}_{\overline{X}}&=\text{E}(X)=\overline{X}\\ T&=\text{target required by customer/board comitee}\\ \text{LCL}_{\overline{X}}&=\overline{\overline{X}}-3\sigma_X\\ \text{LSL}&=\text{required by customer/board comitee}\end{aligned} \quad (16.7.828)$$

and we can get rid of the of the estimation problem of σ_X using the relation proved in the section Statistics during our study of range statistics (see section Statistics page 1203):

$$\overline{R}=\sigma_X d_2(n_i) \quad (16.7.829)$$

Therefore rearranging and using the prior previous relation:

$$\boxed{\sigma_X=\frac{\overline{R}}{d_2(n_i)}=\frac{\text{MR}}{d_2(n_i)}} \quad (16.7.830)$$

It comes (it is impossible that the customer sets a limit for the USL, LSL or target T as regards the range as in general it is asymmetric, hence the fact that these parameters are this time not listed):

$$\begin{aligned}\text{UCL}_{\overline{X}(\text{MR})}&=\overline{X}+3\frac{\overline{\text{MR}}}{d_2(n_i)}\\ \text{CL}_{\overline{X}(\text{MR})}&=\overline{R}\\ \text{LCL}_{\overline{X}(\text{MR})}&=\overline{X}-3\frac{\overline{\text{MR}}}{d_2(n_i)}\end{aligned} \quad (16.7.831)$$

Remark

The same unbiasing constant can be used for subgroup control charts! Indeed, rather than using $R_i=x_{i-1}-x_i$ we use $R_i=\overline{X}_{i-1}-\overline{X}_i$ where i is then the number of the sample!!! This is why in fact Minitab propose in the menu of *Measurement subgroup control charts* the MR chart!!!

As companion example let us consider the following data:

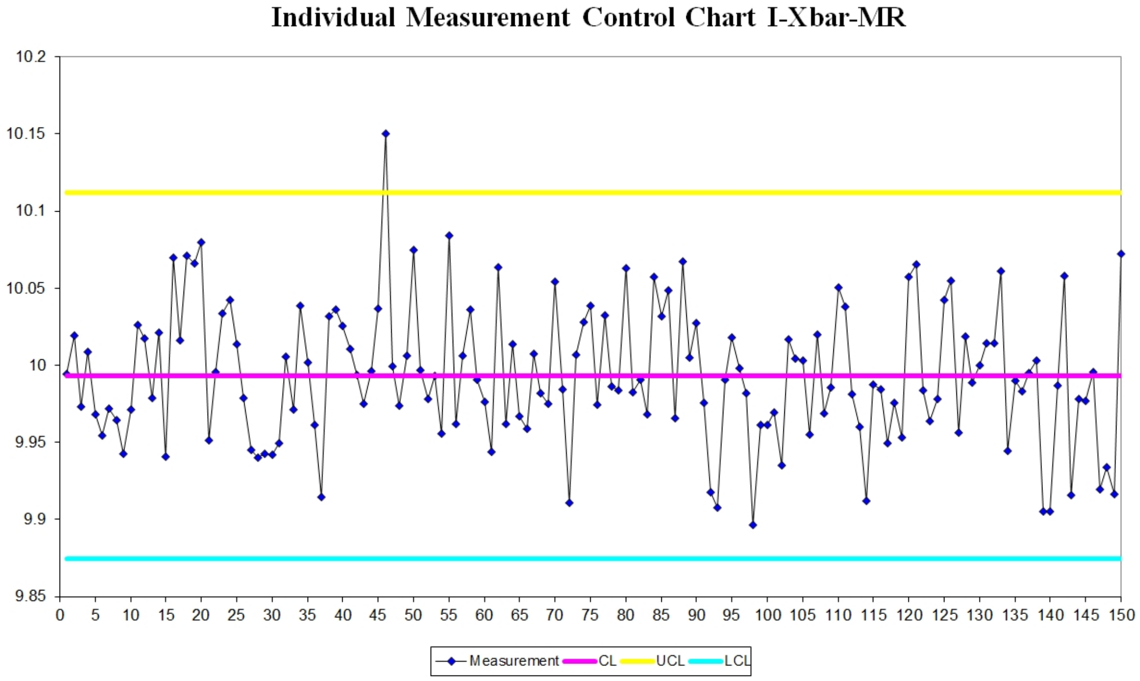
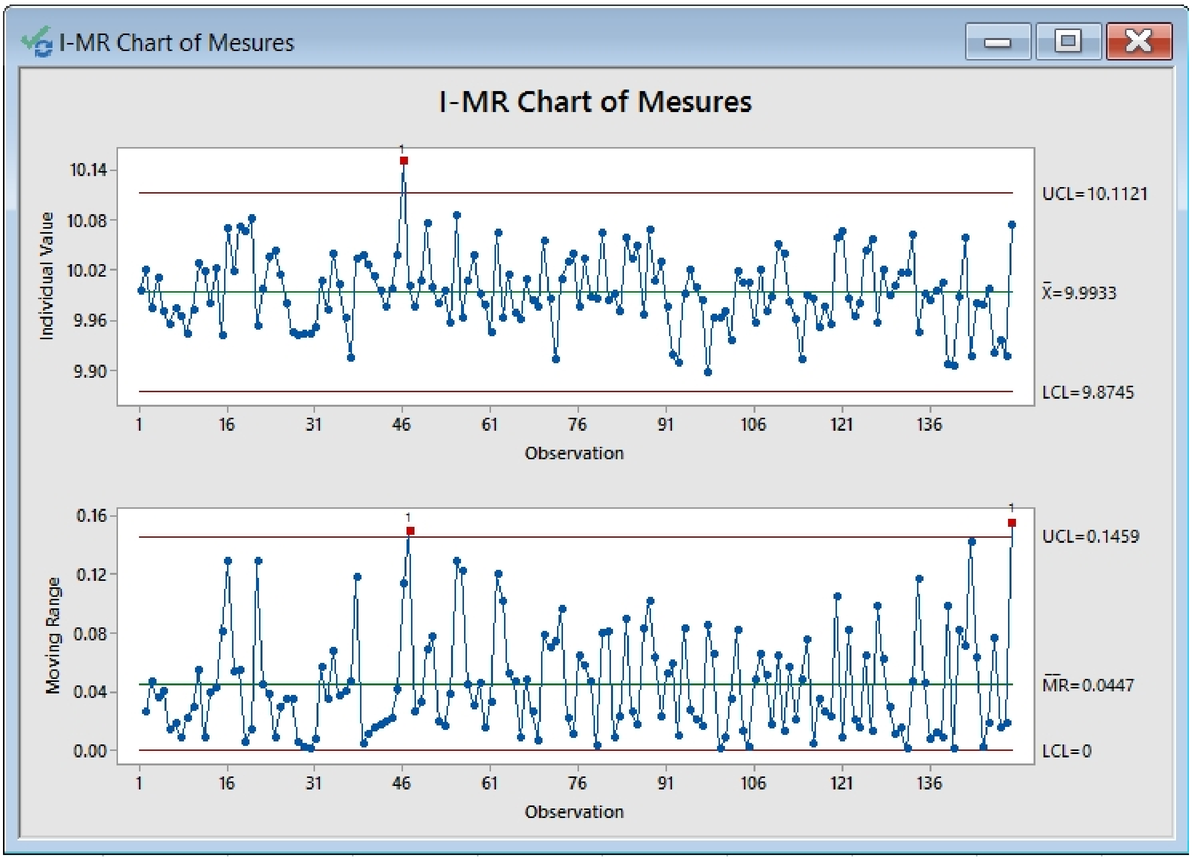
Then we have the following chart:



With Minitab 17.1.3 this gives for people that don't trust our calculations made with Microsoft® Excel®:



Notice that this control chart would have according to the WECO rules 1 point beyond the $\pm 3\sigma$ (we indicate that for comparison reasons with previous control charts and the next one).

As the reader has probably noticed it in the figure above, Minitab also plots at the same time an I-MR/$\overline{\text{MR}}$ control chart. So let us study this one just now:

16.7.6.5.2 $\text{I}-\text{MR}/\overline{\text{MR}}$ Individual moving range measurement control chart

So as we just said and noticed it, the previous central tendency control chart must be completed (same normally as for almost all previous control charts with central tendency) with a control chart showing the tendency of dispersion (the benefits and problems of this control chart are the same as the previous one).

Then we take the definitions of a measurement control chart to get:

$$\begin{aligned}\text{UCL}_{\text{MR}} &= \overline{\text{MR}} + 3\sigma_{\overline{\text{MR}}}\\ \text{CL}_{\text{MR}} &= \overline{\text{MR}}\\ \text{LCL}_{\text{MR}} &= \overline{\text{MR}} - 3\sigma_{\overline{\text{MR}}}\end{aligned} \tag{16.7.832}$$

Again, the standard deviation of the moving range (MR) is constructed in the same way as the standard deviation of the range. Then we have:

$$\sigma_{\text{MR}} = \frac{d_3(n_i)\overline{\text{MR}}}{d_2(n_i)} \tag{16.7.833}$$

It comes (it is impossible that the customer sets a limit for the USL, LSL or target T as regards the range as in general it is asymmetric, hence the fact that these parameters are this time not listed):

$$\begin{aligned}
\text{UCL}_{\text{MR}} &= \overline{\text{MR}} + 3\sigma_{\overline{\text{MR}}} = \overline{\text{MR}} + 3\frac{d_3(n_i)\overline{\text{MR}}}{d_2(n_i)} = \overline{\text{MR}}\left(1 + 3\frac{d_3(n_i)}{d_2(n_i)}\right) \\
\text{CL}_{\text{MR}} &= \overline{\text{MR}} \\
\text{LCL}_{\text{MR}} &= \overline{\text{MR}} - 3\sigma_{\overline{\text{MR}}} = \overline{\text{MR}} - 3\frac{d_3(n_i)\overline{\text{MR}}}{d_2(n_i)} = \overline{\text{MR}}\left(1 - 3\frac{d_3(n_i)}{d_2(n_i)}\right)
\end{aligned} \tag{16.7.834}$$

which is denoted as well as the range control chart:

$$\boxed{\begin{aligned}
\text{UCL}_{\text{MR}} &= \overline{\text{MR}}D_4(n_i) \\
\text{CL}_{\text{MR}} &= \overline{\text{MR}} \\
\text{LCL}_{\text{MR}} &= \overline{\text{MR}} - 3\sigma_{\overline{\text{MR}}} = \overline{\text{MR}}D_3(n_i)
\end{aligned}} \tag{16.7.835}$$

with for recall:

$$\boxed{D_4 = 1 + 3\frac{d_3(n_i)\overline{R}}{d_2(n_i)} \qquad D_3 = 1 - 3\frac{d_3(n_i)\overline{R}}{d_2(n_i)}} \tag{16.7.836}$$

As companion example let us consider the following data:

	A	B	C	D	E	F	G

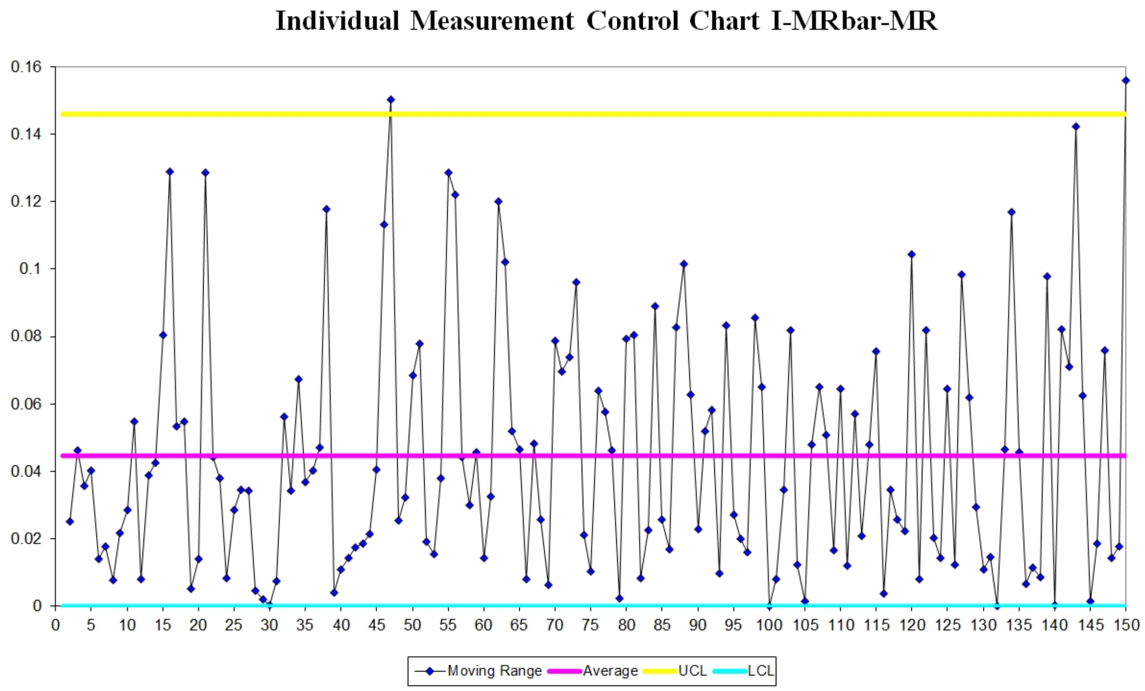
Then we have the following chart:



We see that this control chart with moving range seems much more sensitive than any previous control chart. But the problem remains as to know whether our observation of this control chart is correct in the sense that the moving range does not follow a symmetrical distribution law at the contrary to what presupposes fixed Shewhart limits.

Also be aware that some of the WECO rules (the rules for sequences for example) do not apply to this type of control chart, since the data are autocorrelated there.

16.7.6.5.3 Individual Moving Average control chart

We always assume here that the characteristic follows a Normal distribution (...) and that the samples were taken of constant size n (yes... Moving Average control charts can also be used for subgroups using moving range standard deviation or S estimation method, not only for individual measurement!!!). The moving average of duration h at time t, written M_t is defined by moving average seen in the section Statistics:

$$M_t=\frac{\overline{X}_t+\overline{X}_{t-1}+\ldots+\overline{X}_{t-h+1}}{h} \tag{16.7.837}$$

The parameter h is also named "horizon". Greater is the value of h better is the efficiency of this control chart for the detection of small deviations.

When $t\geq h$, assuming independence between samples, we get using the property of the variance:

$$\begin{aligned}\mathrm{V}(M_t)&=\mathrm{V}\left(\frac{\overline{X}_t+\overline{X}_{t-1}+\ldots+\overline{X}_{t-h+1}}{h}\right)=\frac{1}{h^2}\mathrm{V}\left(\overline{X}_t+\overline{X}_{t-1}+\ldots+\overline{X}_{t-h+1}\right)\\&=\frac{1}{h^2}\sum_{i=t-h+1}^{t}\mathrm{V}\left(\overline{X}_i\right)=\frac{1}{h^2}\sum_{i=t-h+1}^{t}\frac{\sigma^2}{n}=\frac{1}{h^2}h\frac{\sigma^2}{n}=\frac{\sigma^2}{hn}\end{aligned} \tag{16.7.838}$$

And if all the samples have the same size (if samples there are...)

$$\text{V}(M_t)=\frac{1}{h^2}\sum_{i=t-h+1}^{t}\text{V}\left(\overline{X}_i\right)=\frac{1}{h^2}\sum_{i=t-h+1}^{t}\frac{\sigma^2}{n}=\frac{1}{h^2}j\frac{\sigma^2}{n}=\frac{\sigma^2}{hn} \tag{16.7.839}$$

Therefore:

$$\sigma_{M_t}=\frac{\sigma}{\sqrt{hn}} \tag{16.7.840}$$

And:

$$\text{E}(M_t)=\text{E}\left(\frac{\overline{X}_t+\overline{X}_{t-1}+\ldots+\overline{X}_{t-h+1}}{h}\right)=\frac{1}{h}\text{E}\left(\overline{X}_t+\overline{X}_{t-1}+\ldots+\overline{X}_{t-h+1}\right)=\frac{1}{h}h\overline{\overline{X}}=\overline{\overline{X}} \tag{16.7.841}$$

So Finally:

$$\boxed{\begin{aligned}\text{UCL}_{\text{MA}}&=M_t+3\frac{\sigma}{\sqrt{hn}}\\ \text{CL}_{\text{MA}}&=\overline{\overline{X}}\\ \text{LCL}_{\text{MA}}&=M_t-3\frac{\sigma}{\sqrt{hn}}\end{aligned}} \tag{16.7.842}$$

Ok this done, let us now as always make a summary of the pros and cons of this control chart.

Pros:

- The fact that we smooth the fluctuations in the purpose to reduce strong variations makes this control chart very well suited for small productions for which the total number of items is around 10 (however as already mentioned this control chart can also be used for subgroup measurement). Also in the example that will follow, we will only focus on this special scenario of individual measurement!
- We also see that the boundaries of this control will be even smaller than h is large. So this control chart can be very sensitive to small variations on the long term.

Cons:

- The standard deviation is assumed to be known or at least calculated precisely so that the estimator converges to the theoretical value. All samples should be of identical size n if we use the method developed above (otherwise most S.P.C. softwares implement the necessary mathematical tools of this condition is not satisfied).

As companion example let us consider the following data:

	A
4	**Items**
5	9.9943
6	10.0196
7	9.9732
8	10.0088
9	9.9685
10	9.9544
11	9.9721
12	9.9643
13	9.9426
14	9.9712
15	10.0259
16	10.0177
17	9.9788
18	10.0213
19	9.9407
20	10.0696
21	10.0161
22	10.0709
23	10.0658

Since the control chart is with individual values, we have $n=1$. And the system using the moving range for the estimate of the standard deviation is reduced to:

$$\boxed{\begin{aligned} \text{UCL}_{\text{MA}} &= \overline{\overline{X}}+3\frac{\sigma}{\sqrt{hn}}=\overline{\overline{X}}+3\frac{\overline{MR}}{d_2(n_i)\sqrt{h}} \\ \text{CL}_{\text{MA}} &= \overline{\overline{X}} \\ \text{LCL}_{\text{MA}} &= \overline{\overline{X}}-3\frac{\sigma}{\sqrt{hn}}=\overline{\overline{X}}-3\frac{\overline{MR}}{d_2(n_i)\sqrt{h}} \end{aligned}} \tag{16.7.843}$$

Therefore apart the denominators with the root of h, the parameters CL, UCL and LCL are the same as the I-MR $\overline{X}$ control chart. So we fall back on the same calculation method as the one provided par the NCSS Statistical Analysis & Graphics Software.

We must take in the case of our special example the value of d_2 for $n_i=2$. The tables or direct calculations give us:

$$d_2(n_i)=d_2(2)=1.128 \tag{16.7.844}$$

Which gives us for the calculations:

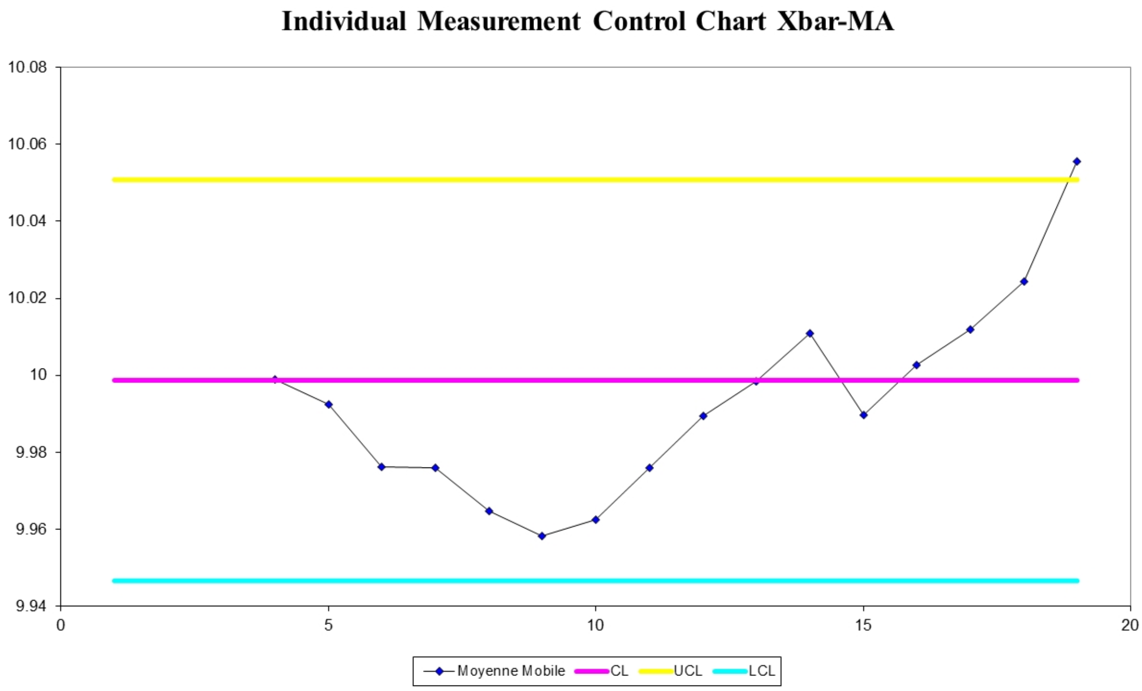
Then we have the following chart:



Notice that this control chart would have according to the WECO rules 1 point beyond the $\pm3\sigma$ based (we indicate that for comparison reasons with previous control charts and the next one).

We don't get the same results with Minitab 17.1.3 (or any known prior version this software) as they seem to use a strange method to calculate the standard deviation for which we can not found any proof (...):

16.7.6.5.4 CUSUM (cumulated sum) control chart with empirical V-mask

A major disadvantage of the control chart of the Shewhart type is to base that analysis on the latest information collected (assumption of independence of measurements). They ignore the information of trends of the process contained in the latest estimates. You should know that many quality standards institutes worldwide (AFNOR or ASQ) consider Shewhart charts as completely obsolete (wrongly or rightly?) and advice the usage of CUSUM control charts because the latter use autocorrelation and amplify the variations.

In the years 11950s (holocene calendar) control charts named "CUSUM (cumulated sum)" or "Page-Hinkley control chart" (in honour of their inventors) were introduced by statisticians to detect small variations. Although they are mathematically more optimal, they are difficult to properly configure and very sensitive to the initial settings.

The principle of CUSUM control charts (because there are several for one given distribution law...) is to sum the differences between the estimates of the position of the method / process and its target. When the accumulated positive variances or accumulated negative variances exceed a certain value, we conclude with a off-centering of the process.

We put:

$$C_n=\sum_{i=1}^{n}(X_i-\mu) \tag{16.7.845}$$

and:

$$S_n=\frac{C_n}{\sigma} \tag{16.7.846}$$

that is obviously a sum of centered reduced variables!

Where often the first equality is written:

$$C_n=\sum_{i=1}^{n}(X_i-\mu)=(X_n-\mu)+\sum_{i=1}^{n-1}(X_i-\mu)=(X_n-\mu)+C_{n-1} \tag{16.7.847}$$

Therefore there comes a famous notation in the literature:

$$S_n=\frac{C_n}{\sigma}=\frac{(X_n-\mu)+C_{n-1}}{\sigma}=\frac{X_n-\mu}{\sigma}+S_{n-1}=Z_n+S_{n-1} \tag{16.7.848}$$

In general, the CUSUM control chart behaves as follows:

- If the process is under control, the cumulative sum fluctuates randomly around zero.
- If the average undergoes a positive drift of the mean, the statistic C_n or S_n grows quick by accumulation of a systematic bias.

Remarks

R1. In many books and numerous application cases, we do not use S_n because the variance is unknown and we restrict ourselves to the use of C_n only. The mathematical developments which then follows can be adapted very easily.

R2. The same approach can be made with average of samples following:

$$C_n = \sum_{i=1}^{n} \left(\overline{X}_i - \mu_{\overline{X}}\right) \qquad \text{and} \qquad S_n = \frac{C_n}{\sigma_{\overline{X}}} \tag{16.7.849}$$

R3. There are many different versions of the CUSUM control charts and this even for the CUSUM with V-mask there are multiple sub-families. To be honest there is in my opinion quite a mess...

For the example, let us take again the following data table:

	A	B	C	D	E	F	G
1		Sample 1	Sample 2	Sample 3	Sample 4	Sample 5	Sample 6
2	Day 1	9.9943	10.0196	9.9732	10.0088	9.9685	9.9544
3	Day 2	9.9721	9.9643	9.9426	9.9712	10.0259	10.0177
4	Day 3	9.9788	10.0213	9.9407	10.0696	10.0161	10.0709
5	Day 4	10.0658	10.08	9.9514	9.9958	10.0338	10.0422
6	Day 5	10.0136	9.9791	9.9449	9.9403	9.9424	9.9421
7	Day 6	9.9495	10.0057	9.9715	10.0388	10.0019	9.9616
8	Day 7	9.9144	10.0321	10.0361	10.0253	10.0109	9.9935
9	Day 8	9.9748	9.9962	10.0369	10.15	9.9996	9.9741
10	Day 9	10.0063	10.0749	9.9971	9.978	9.9934	9.9555
11	Day 10	10.084	9.9619	10.0063	10.0364	9.9907	9.9762
12	Day 11	9.9436	10.0638	9.9617	10.0138	9.9672	9.9591
13	Day 12	10.0074	9.9817	9.9753	10.0541	9.9845	9.9107
14	Day 13	10.0069	10.0282	10.0385	9.9747	10.0323	9.986
15	Day 14	9.9836	10.063	9.9824	9.9909	9.9684	10.0575
16	Day 15	10.0317	10.0485	9.9659	10.0675	10.0047	10.0277
17	Day 16	9.9756	9.9174	9.9076	9.9909	10.018	9.9979
18	Day 17	9.9818	9.8962	9.9614	9.9612	9.9694	9.9349
19	Day 18	10.0168	10.0043	10.0029	9.9549	10.0199	9.9691
20	Day 19	9.9857	10.0503	10.0381	9.9811	9.9603	9.9123
21	Day 20	9.9878	9.9841	9.9496	9.9754	9.9532	10.0576
22	Day 21	10.0657	9.9838	9.9636	9.9779	10.0423	10.0547
23	Day 22	9.9564	10.0184	9.989	9.9999	10.0146	10.0145
24	Day 23	10.0611	9.9443	9.9899	9.9833	9.9947	10.0033
25	Day 24	9.9054	9.9049	9.987	10.058	9.9156	9.9782
26	Day 25	9.9768	9.9954	9.9196	9.9341	9.9162	10.0721

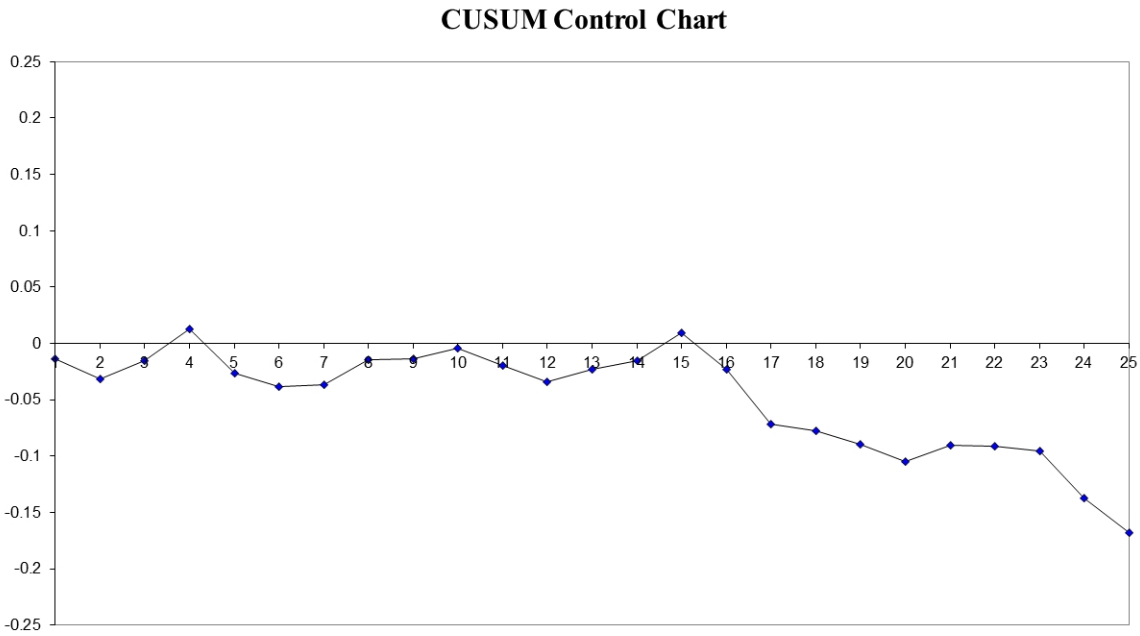
and we calculate the cumulative quantity still considering a target $\mu = T = 10$:

	I	J	K
1	**Points**	**Average-Target**	**Ci**
2	1	-0.0135	-0.0135
3	2	-0.0177	-0.0312
4	3	0.0162	-0.0150
5	4	0.0282	0.0132
6	5	-0.0396	-0.0264
7	6	-0.0118	-0.0383
8	7	0.0020	-0.0362
9	8	0.0219	-0.0143
10	9	0.0009	-0.0134
11	10	0.0092	-0.0042
12	11	-0.0151	-0.0193
13	12	-0.0144	-0.0337
14	13	0.0111	-0.0226
15	14	0.0076	-0.0150
16	15	0.0243	0.0094
17	16	-0.0321	-0.0227
18	17	-0.0492	-0.0719
19	18	-0.0053	-0.0773
20	19	-0.0120	-0.0893
21	20	-0.0154	-0.1047
22	21	0.0147	-0.0900
23	22	-0.0012	-0.0912
24	23	-0.0039	-0.0951
25	24	-0.0418	-0.1369
26	25	-0.0310	-0.1679

Thus explicitly:

	I	J	K	L	M
1	**Points**	**Average-Target**	**C_i**		**Target**
2	1	=AVERAGE(B2:G2)-$M$2	=J2		10
3	2	=AVERAGE(B3:G3)-$M$2	=K2+J3		**h**
4	3	=AVERAGE(B4:G4)-$M$2	=K3+J4		1
5	4	=AVERAGE(B5:G5)-$M$2	=K4+J5		**d**
6	5	=AVERAGE(B6:G6)-$M$2	=K5+J6		0.05
7	6	=AVERAGE(B7:G7)-$M$2	=K6+J7		**K**
8	7	=AVERAGE(B8:G8)-$M$2	=K7+J8		=M6/2
9	8	=AVERAGE(B9:G9)-$M$2	=K8+J9		
10	9	=AVERAGE(B10:G10)-$M$2	=K9+J10		
11	10	=AVERAGE(B11:G11)-$M$2	=K10+J11		
12	11	=AVERAGE(B12:G12)-$M$2	=K11+J12		
13	12	=AVERAGE(B13:G13)-$M$2	=K12+J13		
14	13	=AVERAGE(B14:G14)-$M$2	=K13+J14		
15	14	=AVERAGE(B15:G15)-$M$2	=K14+J15		
16	15	=AVERAGE(B16:G16)-$M$2	=K15+J16		
17	16	=AVERAGE(B17:G17)-$M$2	=K16+J17		
18	17	=AVERAGE(B18:G18)-$M$2	=K17+J18		
19	18	=AVERAGE(B19:G19)-$M$2	=K18+J19		
20	19	=AVERAGE(B20:G20)-$M$2	=K19+J20		
21	20	=AVERAGE(B21:G21)-$M$2	=K20+J21		
22	21	=AVERAGE(B22:G22)-$M$2	=K21+J22		
23	22	=AVERAGE(B23:G23)-$M$2	=K22+J23		
24	23	=AVERAGE(B24:G24)-$M$2	=K23+J24		
25	24	=AVERAGE(B25:G25)-$M$2	=K24+J25		
26	25	=AVERAGE(B26:G26)-$M$2	=K25+J26		

Then we have the following chart:



We then very quickly see with this control chart that the cumulate sum seems to decrease. This indicates that the true mean quality is lower than the target (you can try with 9.994 as the target to see the sensitivity).

We must now consider two cases:

H1. It comes under the assumption of normality (process under control) and by the property of stability of the Normal distribution for a centered reduced random variable:

$$S_i = \mathcal{N}(\mu,\sigma) = \mathcal{N}\left(0,\sqrt{i}\right) \tag{16.7.850}$$

or otherwise:

$$C_n = \mathcal{N}(\mu,\sigma) = \mathcal{N}\left(0,\sigma\sqrt{i}\right) \tag{16.7.851}$$

Therefore, under this hypothesis, we have the cumulative sums $(S_i)_{i=1\ldots n}$ which are distributed around a regression line of slope 0 (since the average of the sums of a random variables with zero mean is zero...) and the distributions have their standard deviation, which is proportional to the root of i (respectively the variance which is proportional to i).

H2. If the process is out of control (global dispersion), there is a moment $t<n$ such as $X_i = \mathcal{N}(\mu,\sigma)$ for $i \leq r-1$ and $X_i = \mathcal{N}(\mu+\delta,\sigma)$ for $i \geq r$ with $\delta > 0$ (the latter value being often imposed by the constraints of quality and named "large middle translation"). Therefore, we have:

$$S_i = \mathcal{N}\left(0,\sqrt{i}\right) \tag{16.7.852}$$

or:

$$C_i = \mathcal{N}\left(0,\sigma\sqrt{i}\right) \tag{16.7.853}$$

for $i=1\ldots r-1$ and:

$$\begin{aligned}S_k-S_{r-1}&=\mathcal{N}\left(\frac{\delta}{\sigma},\sqrt{k}\right)-\mathcal{N}\left(0,\sqrt{r-1}\right)=\mathcal{N}\left(0,\sqrt{r-1}\right)\\&=\mathcal{N}\left(\frac{\delta}{\sigma}+0,\sqrt{\left(\sqrt{k}\right)^2+\left(\sqrt{r-1}\right)^2}\right)=\mathcal{N}\left(\frac{\delta}{\sigma}+0,\sqrt{k+(r-1)}\right)\end{aligned} \tag{16.7.854}$$

for $k\geq r$. That said, it is obvious that the cumulative sums:

$$S_k=\mathcal{N}\left(\frac{\delta}{\sigma},\sqrt{k}\right) \tag{16.7.855}$$

are arranged around regression line of slope δ/σ right from the moment r.

Respectively we have:

$$C_k=\mathcal{N}\left(\delta,\sigma\sqrt{k}\right) \tag{16.7.856}$$

To continue, the idea is to discriminate hypothesis H1 of a regression line of zero slope and the hypothesis H2 of a regression line of δ/σ for S_k by fixing for imaginary border the half of the slope (the right middle in other words...):

$$K_S=\frac{\delta}{2\sigma} \tag{16.7.857}$$

respectively:

$$K_C=\frac{\delta}{2} \tag{16.7.858}$$

and a shift (offset) $h\geq 0$ also empirical with $h\in\mathbb{N}$. At the step n we reject H1 if for an integer $m\leq n$, we have:

$$S_m\geq(n-m)K_S+S_1+hK_S \tag{16.7.859}$$

It is obviously also possible to do it by reject with a geometrical representation (this has the advantage of going much faster and to the control in one time only for any m less than or equal to n). The idea then is to draw a line of slope K starting from the point of abscissa $n+1h$. If there exist a point (m,S_m) with $m<n$ below the regression line, then we pull an alarm.

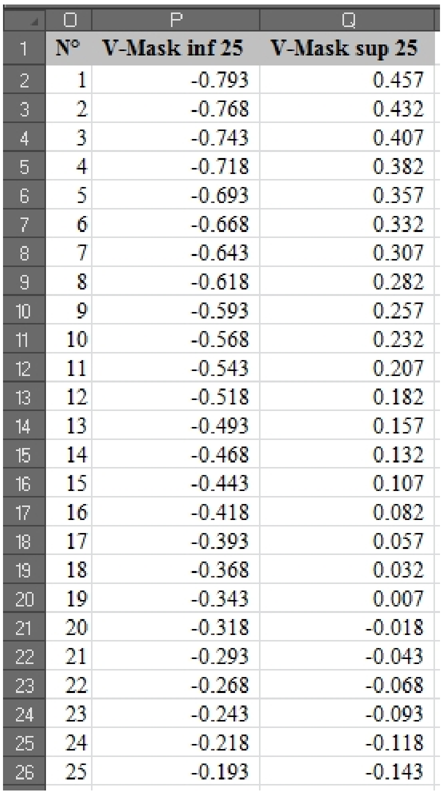
Let us do an example with the previous graph. Consider the following empirical values of the parameters:

$$\delta=0.05\qquad\text{and}\qquad h=1 \tag{16.7.860}$$

Thus:

$$K_C=0.025 \tag{16.7.861}$$

Therefore:



N°	V-Mask inf 25	V-Mask sup 25

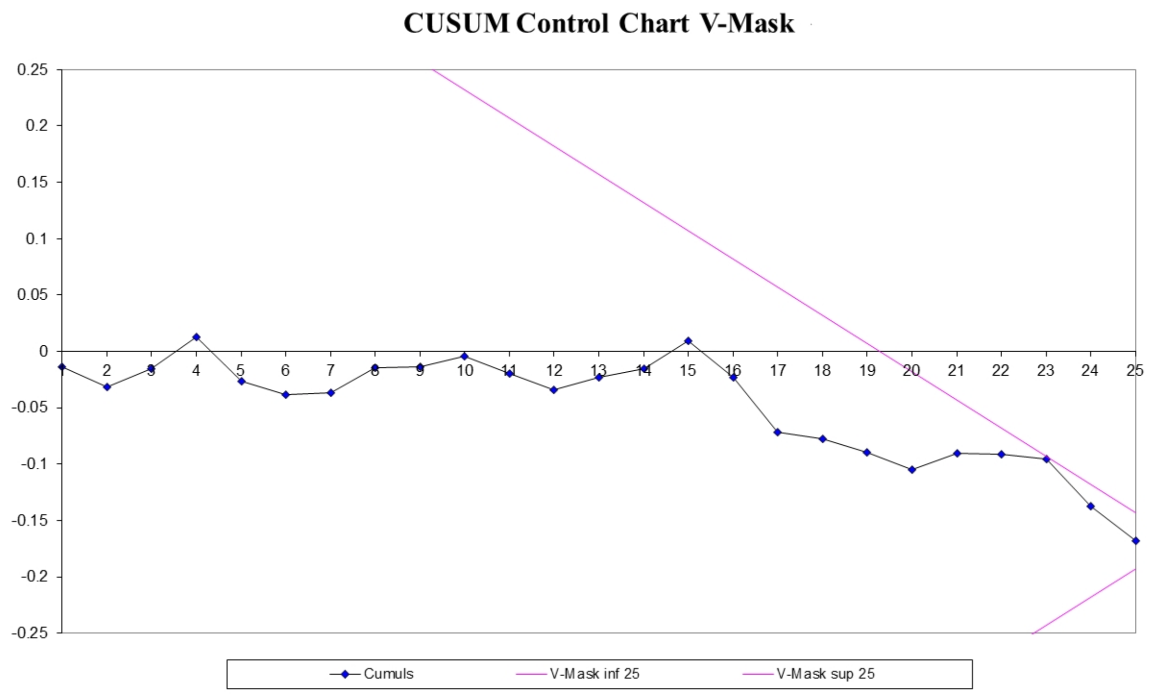
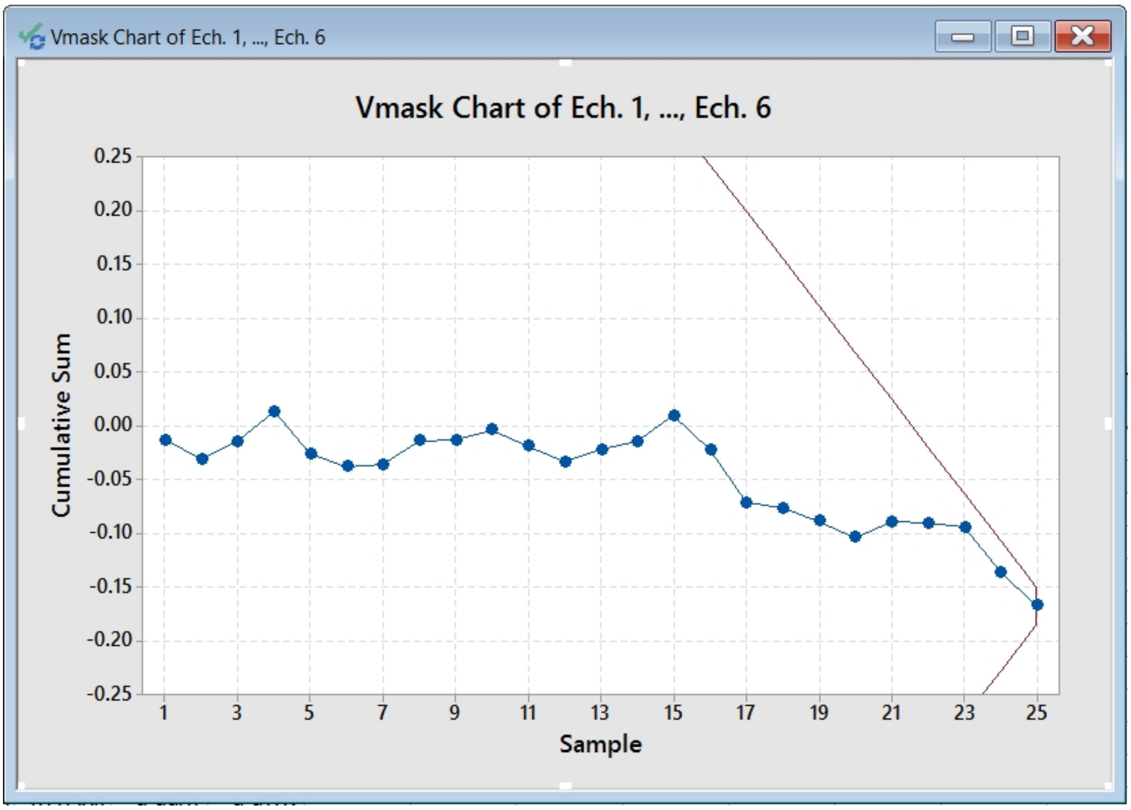
25	=-($O$26-O26)*$M$8+$K$26-$M$4*$M$8	=($O$26-O26)*$M$8+$K$26+$M$4*$M$8

We then havefor example at the point 26 corresponding to $25+h$:



With Minitab 17.1.3 this gives for people that don't trust our calculations made with Microsoft® Excel®:



The reader can easily observe that with the choice we made, we would have no alarm with the selected empirical parameters. It would be necessary in practice to reduce the value δ.

To resume, the benefits of CUSUM control charts compared to Shewhart control charts are:

- They are more effective for detecting small drifts
- The drift of the process visually appears on the control chart
- It is usually easy to detect at what point the process began to drift

The disadvantages of these control charts are the following:

- They can be slow to detect large drifts
- They are not very interesting to analyse past data or to look for cycles or find some type characteristics in the studied distribution.
- They are less easily accepted by operators as less intuitive and do not directly represent the characteristic of interest.

For the reasons discussed above, it is advisable to represent in parallel of CUSUM control charts a classical Shewhart control chart.

Remark

There are still other CUSUM V-mask type. So be careful with the software you use to be sure what you are doing!!!

16.7.6.5.5 EWMA control charts (exponential weighted moving average) with fixed limits

An interesting alternative to the CUSUM control charts in the context of autocorrelation and the detection of small deviations are the EWMA (Exponentially Weighted Moving Average) control charts that have their origin in the field of Time Series Analysis (see section Economy page 7896).

Remark

Some also use control charts using empirical techniques like the simple or double moving average as discussed in section Economy when data are serially correlated.

An EWMA control chart is easy to implement and is not too sensitive to parameter changes and non-Normal data, it remains just as powerful as the CUSUM control charts to detect small variations.

By definition, the statistics reported on a EWMA control chart are calculated by the following equation (notice that the indices of the different terms are not the same as exponential smoothing of a time series as seen in the section Economy at page 7928 since the goal is not to make predictions !!):

$$F_t = \lambda \overline{X}_t + (1-\lambda)F_{t-1} \qquad \forall \lambda \in]0.6, 0.8[\tag{16.7.862}$$

with the particularity that some softwares (like Minitab) take for this control chart:

$$F_0=\overline{X}_1 \quad \text{or} \quad F_0=\overline{X} \tag{16.7.863}$$

The constant λ (smoothing constant) determines the weight that we want to assign to the latest measures. The smallest is this value, more the control chart is sensitive to sudden deviations.

Let us prove that the last relation can be written as:

$$F_t=\left(\sum_{i=0}^{t-1}\lambda(1-\lambda)^i\overline{X}_{t-i}\right)+(1-\lambda)^tF_0 \tag{16.7.864}$$

Indeed:

$$\begin{aligned}F_t&=\lambda\overline{X}_t+(1-\lambda)F_{t-1}=\lambda\overline{X}_t+(1-\lambda)\left(\lambda\overline{X}_{t-1}+(1-\lambda)F_{t-2}\right)\\&=\lambda\overline{X}_t+(1-\lambda)\left(\lambda\overline{X}_{t-1}+(1-\lambda)\left(\lambda\overline{X}_{t-2}+(1-\lambda)F_{t-3}\right)\right)\\&=\left(\sum_{i=0}^{t-1}\lambda(1-\lambda)\overline{X}_{t-1}\right)+(1-\lambda)^tF_0\end{aligned} \tag{16.7.865}$$

Let us suppose for what will follow that:

$$X_i=\mathcal{N}(\mu,\sigma) \tag{16.7.866}$$

Then we have:

$$\text{V}(F_t)=\text{V}\left(\left(\sum_{i=0}^{t-1}\lambda(1-\lambda)^i\overline{X}_{t-1}\right)+(1-\lambda)^tF_0\right) \tag{16.7.867}$$

and remembering one of the properties of the variance (see section Statistics page 596):

$$\text{V}(a\overline{X})=a^2\text{V}\left(\overline{X}\right) \tag{16.7.868}$$

It comes:

$$\begin{aligned}\text{V}(F_t)&=\left(\sum_{i=0}^{t-1}\lambda^2(1-\lambda)^{2i}\text{V}(\overline{X}_{t-i})\right)+(1-\lambda)^{2t}\text{V}(F_0)\\&=\left(\sum_{i=0}^{t-1}\lambda^2(1-\lambda)^{2i}\text{V}(\overline{X}_{t-i})\right)+(1-\lambda)^{2t}\cdot 0\\&=\sum_{i=0}^{t-1}\lambda^2(1-\lambda)^{2i}\text{V}(\overline{X}_{t-i})=\lambda^2\sum_{i=0}^{t-1}(1-\lambda)^{2i}\sigma^2=\lambda^2\sigma^2\sum_{i=0}^{t-1}(1-\lambda)^{2i}\end{aligned} \tag{16.7.869}$$

Let us do a change of variable:

$$x=(1-\lambda)^2 \tag{16.7.870}$$

Then it comes using the result proved in the context of our study of arithmetic sequences in the section of Sequences and Series (see page 1679):

$$\begin{aligned}\text{V}(F_t)&=\lambda^2\sigma^2\sum_{i=0}^{t-1}x^i=\lambda^2\sigma^2\frac{1-x^{(t-1)+1}}{1-x}=\lambda^2\sigma^2\frac{1-(1-\lambda)^{2t}}{1-(1-\lambda)^2}\\&=\lambda^2\sigma^2\frac{1-(1-\lambda)^{2t}}{1-1+2\lambda+\lambda^2}=\sigma^2\frac{\lambda^2}{2\lambda+\lambda^2}\left(1-(1-\lambda)^{2t}\right)\\&=\sigma^2\frac{\lambda}{2+\lambda}\left(1-(1-\lambda)^{2t}\right)\end{aligned} \tag{16.7.871}$$

when t is sufficiently large, then the variance is reduced to (approximation that the majority of softwares - like Minitab - don't do and therefore the limits are not constant depending on t!):

$$\text{V}(F_t)=\sigma_{F_t}^2\cong\sigma^2\frac{\lambda}{2+\lambda} \tag{16.7.872}$$

the EWMA control charts limits then are also build with the $\pm\sigma$:

$$\sigma_{\text{EWMA}}=\sigma\sqrt{\frac{\lambda}{2+\lambda}} \tag{16.7.873}$$

We therefore have when a target and also a standard deviation are defined (it is impossible that the customer sets a LSL, USL or target T regarding to the exponential weighting hence the fact that these parameters are this time not listed):

$$\boxed{\begin{aligned}\text{UCL}_{\text{EWMA}}&=\overline{\overline{X}}+3\frac{\sigma}{\sqrt{n_i}}\sqrt{\frac{\lambda}{2+\lambda}}=\overline{\overline{X}}+3\sigma\sqrt{\frac{\lambda}{n_i(2+\lambda)}}\\ \text{CL}_{\text{EWMA}}&=\overline{\overline{X}}\\ \text{LCL}_{\text{EWMA}}&=\overline{\overline{X}}-3\frac{\sigma}{\sqrt{n_i}}\sqrt{\frac{\lambda}{2+\lambda}}=\overline{\overline{X}}-3\sigma\sqrt{\frac{\lambda}{n_i(2+\lambda)}}\end{aligned}} \tag{16.7.874}$$

Some softwares uses to calculate the standard deviation the following relation that we have proved earlier above:

$$\sigma=\frac{\overline{R}}{d_2(n_i)} \tag{16.7.875}$$

and others (such as Minitab):

$$\sigma=\frac{\overline{\text{MR}}}{d_2(2)} \tag{16.7.876}$$

the latter option has the advantage of working if the sample size is unitary (we speak then of course "EWMA for individual values"). Let us recall that in fact we have already mentioned that the EWMA control chart is poorly suited to mass production.

It should be noticed that regardless of the option chosen, as we have:

$$\sqrt{\frac{\lambda}{2+\lambda}}<1 \tag{16.7.877}$$

the controls limits are always significantly below those of a range or moving range control chart. This is also a reason why we smooth the data!

Let us do an example for each variant of calculation of the standard deviation since each is of equal importance in practice. To do this, let us start with the EWMA control chart with:

$$\begin{aligned}\text{UCL}_{\text{EWMA}}&=\overline{\overline{X}}+3\frac{\overline{R}}{d_2(n_i)}\sqrt{\frac{\lambda}{n_i(2+\lambda)}}\\ \text{CL}_{\text{EWMA}}&=\overline{\overline{X}}\\ \text{LCL}_{\text{EWMA}}&=\overline{\overline{X}}-3\frac{\overline{R}}{d_2(n_i)}\sqrt{\frac{\lambda}{n_i(2+\lambda)}}\end{aligned} \tag{16.7.878}$$

and taking the following table of data:

	A	B	C	D	E	F	G
4		Sample 1	Sample 2	Sample 3	Sample 4	Sample 5	Sample 6
5	Day 1	9.9943	10.0196	9.9732	10.0088	9.9685	9.9544
6	Day 2	9.9721	9.9643	9.9426	9.9712	10.0259	10.0177
7	Day 3	9.9788	10.0213	9.9407	10.0696	10.0161	10.0709
8	Day 4	10.0658	10.08	9.9514	9.9958	10.0338	10.0422
9	Day 5	10.0136	9.9791	9.9449	9.9403	9.9424	9.9421
10	Day 6	9.9495	10.0057	9.9715	10.0388	10.0019	9.9616
11	Day 7	9.9144	10.0321	10.0361	10.0253	10.0109	9.9935
12	Day 8	9.9748	9.9962	10.0369	10.15	9.9996	9.9741
13	Day 9	10.0063	10.0749	9.9971	9.978	9.9934	9.9555
14	Day 10	10.084	9.9619	10.0063	10.0364	9.9907	9.9762
15	Day 11	9.9436	10.0638	9.9617	10.0138	9.9672	9.9591
16	Day 12	10.0074	9.9817	9.9753	10.0541	9.9845	9.9107
17	Day 13	10.0069	10.0282	10.0385	9.9747	10.0323	9.986
18	Day 14	9.9836	10.063	9.9824	9.9909	9.9684	10.0575

We get:

	I	J	K	L	M	N	O
1	**λ**	0.6000					
2	**d2**	2.534					
3							
4	**N°**	**Measurements**	**Range**	**EWMA**	**CL**	**LCL**	**UCL**
5	0	9.9865	0.0652	9.98647	9.9989	9.9735	10.0243
6	1	9.9823	0.0833	9.98397	9.9989	9.9735	10.0243
7	2	10.0162	0.1302	10.00333	9.9989	9.9735	10.0243

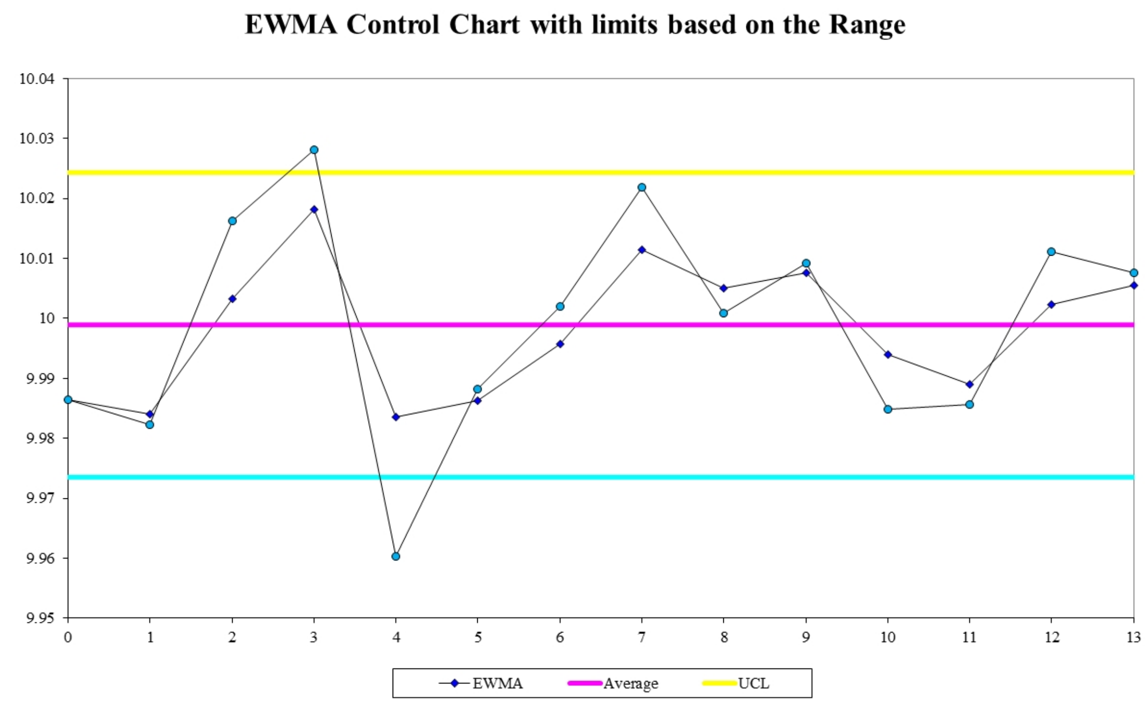
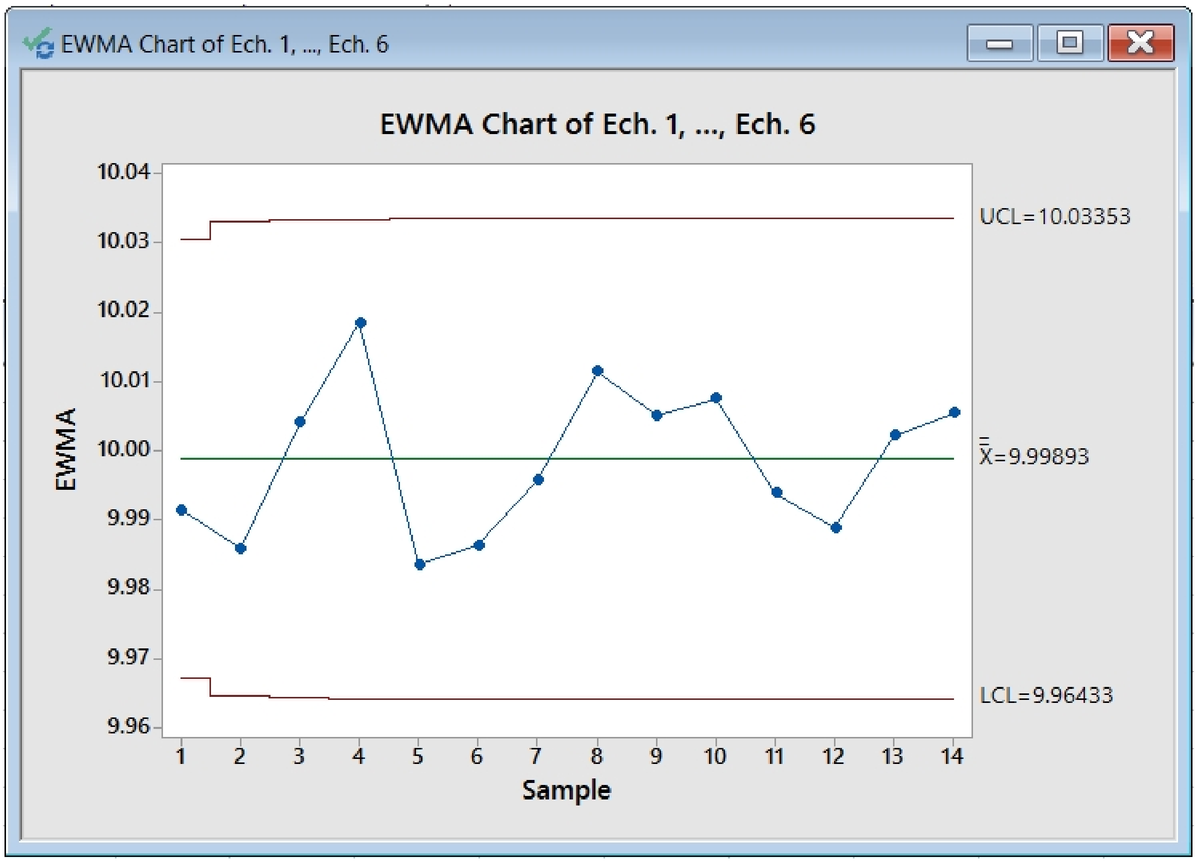
and for the second part:

	N	O
1		
2		
3		
4	**LCL**	**UCL**
5	=M5-3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B5:G5)*(2+$J$1)))	=M5+3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B5:G5)*(2+$J$1)))
6	=M6-3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B6:G6)*(2+$J$1)))	=M6+3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B6:G6)*(2+$J$1)))
7	=M7-3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B7:G7)*(2+$J$1)))	=M7+3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B7:G7)*(2+$J$1)))
8	=M8-3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B8:G8)*(2+$J$1)))	=M8+3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B8:G8)*(2+$J$1)))
9	=M9-3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B9:G9)*(2+$J$1)))	=M9+3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B9:G9)*(2+$J$1)))
10	=M10-3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B10:G10)*(2+$J$1)))	=M10+3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B10:G10)*(2+$J$1)))
11	=M11-3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B11:G11)*(2+$J$1)))	=M11+3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B11:G11)*(2+$J$1)))
12	=M12-3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B12:G12)*(2+$J$1)))	=M12+3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B12:G12)*(2+$J$1)))
13	=M13-3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B13:G13)*(2+$J$1)))	=M13+3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B13:G13)*(2+$J$1)))
14	=M14-3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B14:G14)*(2+$J$1)))	=M14+3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B14:G14)*(2+$J$1)))
15	=M15-3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B15:G15)*(2+$J$1)))	=M15+3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B15:G15)*(2+$J$1)))
16	=M16-3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B16:G16)*(2+$J$1)))	=M16+3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B16:G16)*(2+$J$1)))
17	=M17-3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B17:G17)*(2+$J$1)))	=M17+3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B17:G17)*(2+$J$1)))
18	=M18-3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B18:G18)*(2+$J$1)))	=M18+3*(AVERAGE($K$5:$K$18)/$J$2)*SQRT($J$1/(COUNT(B18:G18)*(2+$J$1)))

We then have the following control chart:



With Minitab 17.3.1 we get a small difference in comparison to our calculations by hand and this is normal as we have made an approximation for a large t and that we also made one of the two choices for F_0:



EWMA Chart of Ech. 1, ..., Ech. 6
EWMA Chart of Ech. 1, ..., Ech. 6
EWMA
10.04
10.03
10.02
10.01
10.00
9.99
9.98
9.97
9.96
1
2
3
4
5
6
7
8
9
10
11
12
13
14
Sample
UCL=10.03353
$\bar{\bar{X}}$=9.99893
LCL=9.96433

For the last example, we take the famous case of an EWMA control chart with individual values

and:

$$\begin{aligned}\text{UCL}_{\text{EWMA}} &= \overline{\overline{X}} + 3\frac{\overline{\text{MR}}}{d_2(n_i)}\sqrt{\frac{\lambda}{n_i(2+\lambda)}}\\ \text{CL}_{\text{EWMA}} &= \overline{\overline{X}}\\ \text{LCL}_{\text{EWMA}} &= \overline{\overline{X}} - 3\frac{\overline{\text{MR}}}{d_2(n_i)}\sqrt{\frac{\lambda}{n_i(2+\lambda)}}\end{aligned} \tag{16.7.879}$$

with the following data:

	A
1	
2	
3	
4	**Measurements**
5	9.9943
6	10.0196
7	9.9732
8	10.0088
9	9.9685
10	9.9544
11	9.9721
12	9.9643

by taking therefore (caution! the n in the following relation is not the same as that in the root containing the smoothing constant!):

$$\overline{\text{MR}} = \overline{R} = \frac{1}{n-1}\sum_{i=2}^{n}\sum_{i=2}^{n}|x_i - x_{i-1}| \tag{16.7.880}$$

and:

$$d_2(2) = 1.128 \tag{16.7.881}$$

as well as:

$$F_0 = \overline{X} \tag{16.7.882}$$

We have then with a smoothing constant of 0.6:

	C	D	E	F	G	H
1	**λ**	0.60				
2	**d2**	1.128				
3						
4	**N°**	**Moving Range**	**EWMA**	**CL**	**LCL**	**UCL**
5	0		9.9893	9.9819	9.9477	10.0161
6	1	0.0253	10.0075	9.9819	9.9477	10.0161
7	2	0.0464	9.9869	9.9819	9.9477	10.0161
8	3	0.0356	10.0000	9.9819	9.9477	10.0161
9	4	0.0403	9.9811	9.9819	9.9477	10.0161
10	5	0.0141	9.9651	9.9819	9.9477	10.0161
11	6	0.0177	9.9693	9.9819	9.9477	10.0161
12	7	0.0078	9.9663	9.9819	9.9477	10.0161

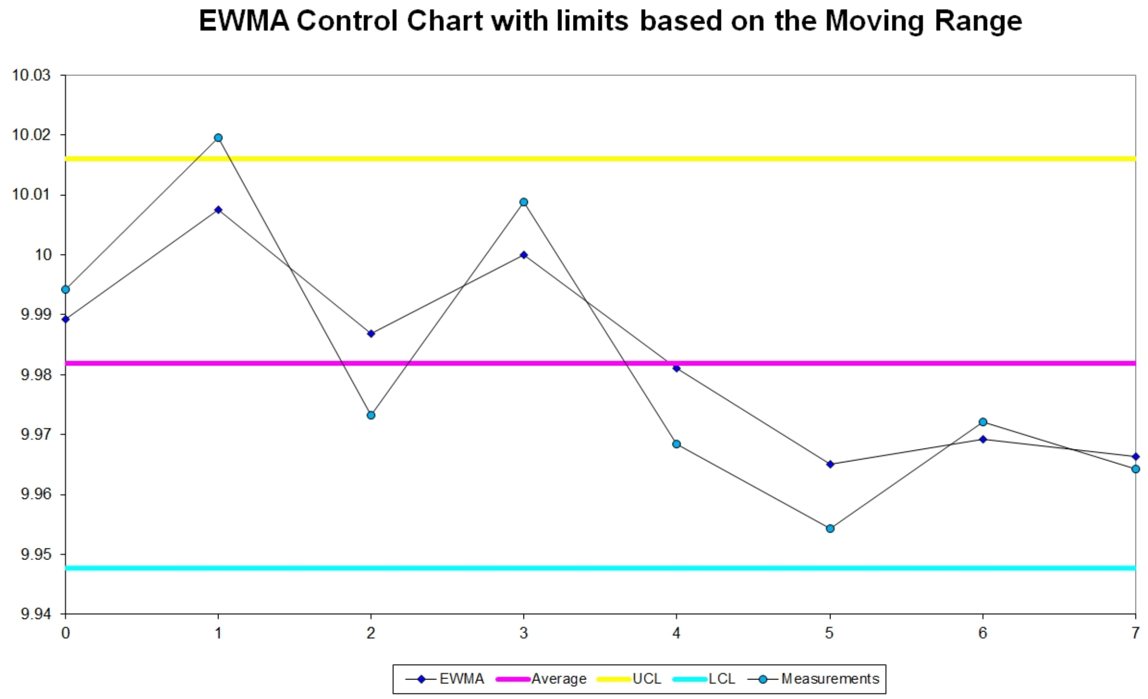
Thus explicitly (we have cut the screenshot below into two parts because of the limit horizontal space on the present page):

	C	D	E	F
1	**λ**	0.6		
2	**d2**	1.128		
3				
4	**N°**	**Moving Range**	**EWMA**	**CL**
5	0		=$D$1*A5+(1-$D$1)*AVERAGE($A$5:$A$12)	=AVERAGE($A$5:$A$12)
6	1	=ABS(A6-A5)	=$D$1*A6+(1-$D$1)*E5	=AVERAGE($A$5:$A$12)
7	2	=ABS(A7-A6)	=$D$1*A7+(1-$D$1)*E6	=AVERAGE($A$5:$A$12)
8	3	=ABS(A8-A7)	=$D$1*A8+(1-$D$1)*E7	=AVERAGE($A$5:$A$12)
9	4	=ABS(A9-A8)	=$D$1*A9+(1-$D$1)*E8	=AVERAGE($A$5:$A$12)
10	5	=ABS(A10-A9)	=$D$1*A10+(1-$D$1)*E9	=AVERAGE($A$5:$A$12)
11	6	=ABS(A11-A10)	=$D$1*A11+(1-$D$1)*E10	=AVERAGE($A$5:$A$12)
12	7	=ABS(A12-A11)	=$D$1*A12+(1-$D$1)*E11	=AVERAGE($A$5:$A$12)

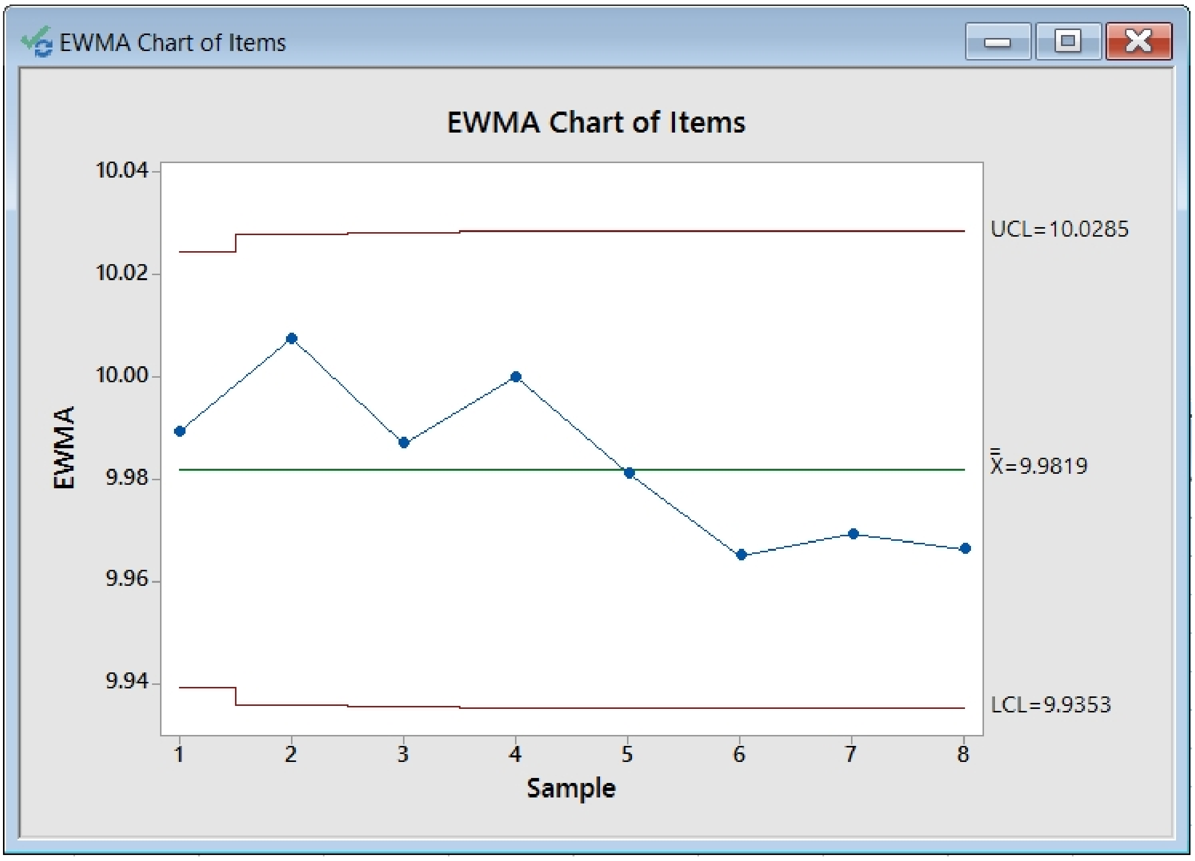
and for the second part:

	G	H
1		
2		
3		
4	**LCL**	**UCL**
5	=F5-3*AVERAGE($D$5:$D$12)/$D$2*SQRT($D$1/(2+$D$1))	=F5+3*AVERAGE($D$5:$D$12)/$D$2*SQRT($D$1/(2+$D$1))
6	=F6-3*AVERAGE($D$5:$D$12)/$D$2*SQRT($D$1/(2+$D$1))	=F6+3*AVERAGE($D$5:$D$12)/$D$2*SQRT($D$1/(2+$D$1))
7	=F7-3*AVERAGE($D$5:$D$12)/$D$2*SQRT($D$1/(2+$D$1))	=F7+3*AVERAGE($D$5:$D$12)/$D$2*SQRT($D$1/(2+$D$1))
8	=F8-3*AVERAGE($D$5:$D$12)/$D$2*SQRT($D$1/(2+$D$1))	=F8+3*AVERAGE($D$5:$D$12)/$D$2*SQRT($D$1/(2+$D$1))
9	=F9-3*AVERAGE($D$5:$D$12)/$D$2*SQRT($D$1/(2+$D$1))	=F9+3*AVERAGE($D$5:$D$12)/$D$2*SQRT($D$1/(2+$D$1))
10	=F10-3*AVERAGE($D$5:$D$12)/$D$2*SQRT($D$1/(2+$D$1))	=F10+3*AVERAGE($D$5:$D$12)/$D$2*SQRT($D$1/(2+$D$1))
11	=F11-3*AVERAGE($D$5:$D$12)/$D$2*SQRT($D$1/(2+$D$1))	=F11+3*AVERAGE($D$5:$D$12)/$D$2*SQRT($D$1/(2+$D$1))
12	=F12-3*AVERAGE($D$5:$D$12)/$D$2*SQRT($D$1/(2+$D$1))	=F12+3*AVERAGE($D$5:$D$12)/$D$2*SQRT($D$1/(2+$D$1))

We then have the following control chart:



With Minitab 17.3.1 we get a small difference in comparison to our calculations by hand and this is normal as we have made an approximation for a large t and also that we made one of the two choices for F_0:



As with other control charts, the EWMA control chart must be accompanied by a control chart for monitoring the variability, so either a control chart based on ranges with fixed limits or a control chart with standard deviations with fixed limits.

16.7.6.6 Rare events control charts

Rare events inherently occur in all kinds of processes. In hospitals, there are medication errors, infections, patient falls, ventilator-associated pneumonias, and other rare, adverse events that cause prolonged hospital stays and increase healthcare costs.

But rare events happen in many other contexts, too. Software developers may need to track errors in lines of programming code, or a quality practitioner may need to monitor a low-defect process in a high-yield manufacturing environment. Accidents that occur on the shop floor and aircraft engine failures are also rare events, ideally.

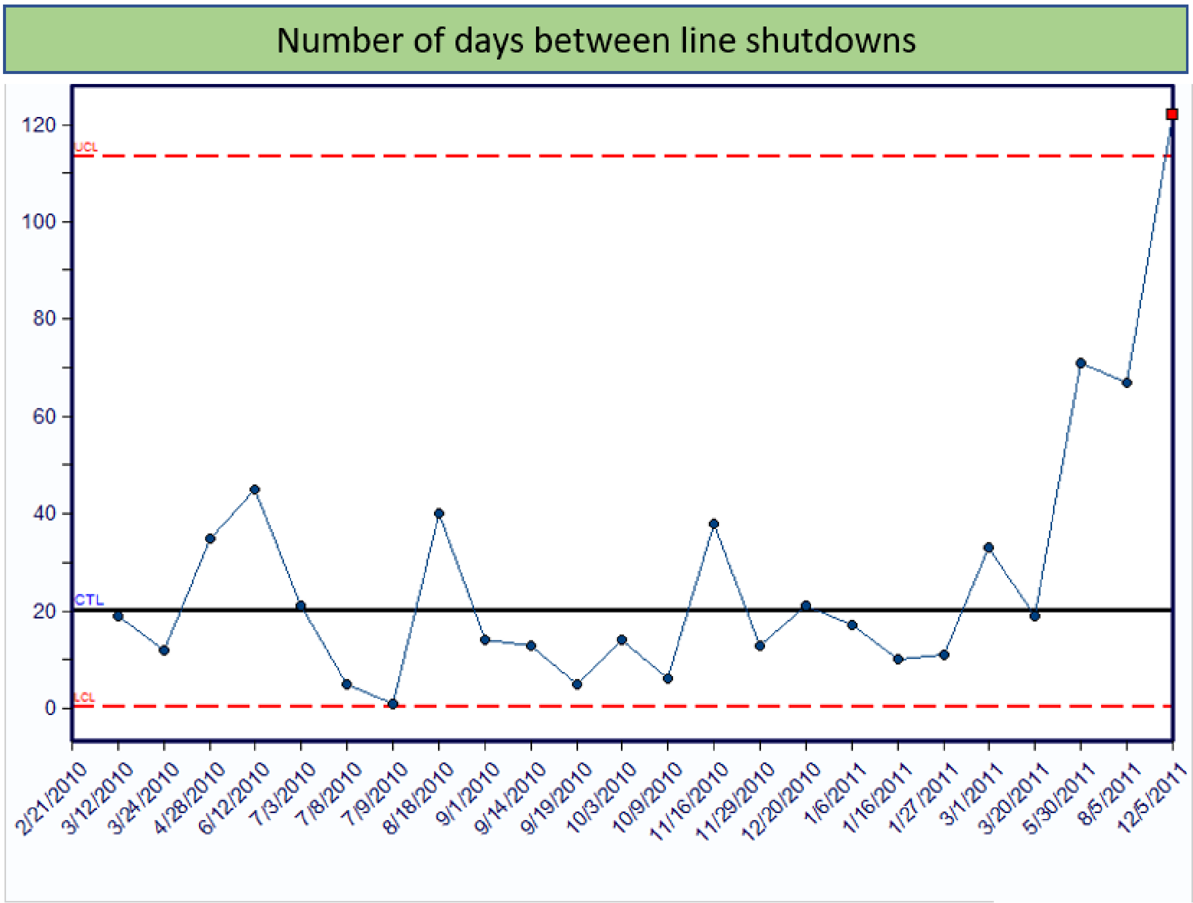
Whether you're in healthcare, software development, manufacturing or some other industry, statistical process control is an important component of quality improvement. Using control charts, we can graph these rare events and monitor a process to determine if it's stable or if it's out of control and therefore unpredictable and in need of attention.

16.7.6.6.1 Frequency T control chart with probabilistic limits

The monitoring of frequency of occurrence of defects / accidents / anomalies is a very simple technique to implement and very easy to read for people with little or no knowledge of statistics. Moreover it is a technique adapted to cases where the monitored events are very rare.

The idea then is not to track the number of special events, but the time T between two appearances of the monitored events. The time T is then measured in either number of pieces or number of accidents, defects, days, etc.

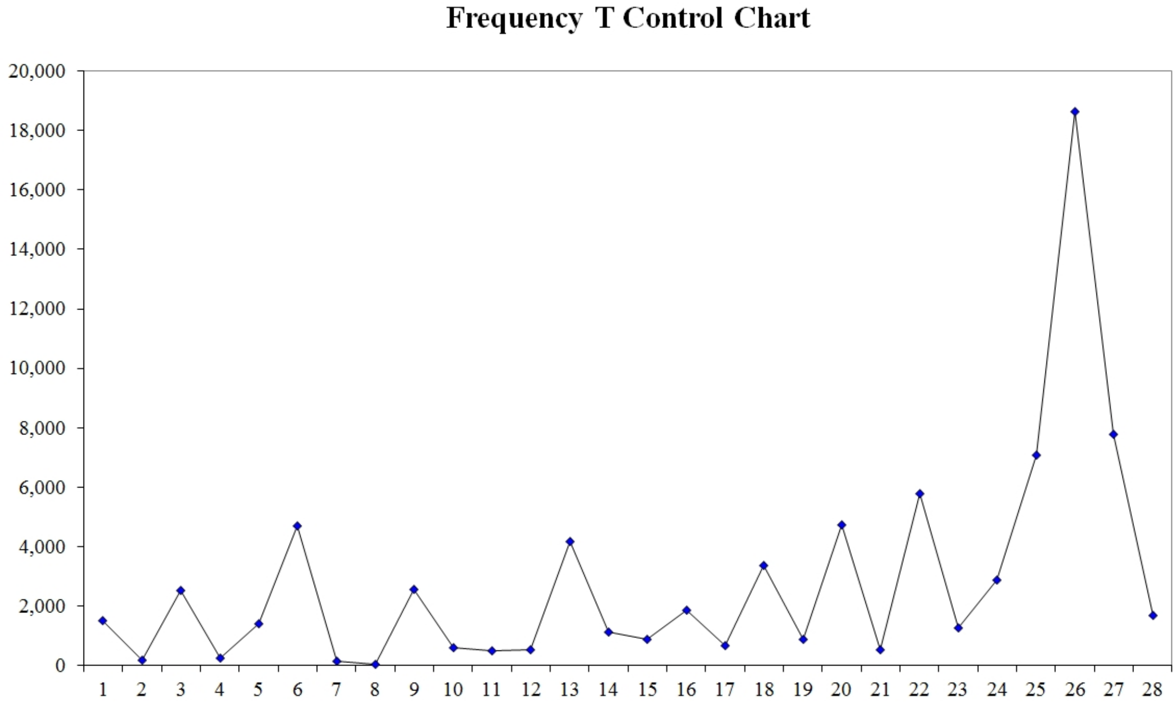
This control chart is also sometimes used by Human Resources departments or Top Managers to track the frequency of problems caused by some employees in the purpose to highlight objectively and scientifically if their behavior is compliant with the expectations of their organization (sadly most C.E.O. and low level managers still don't know such a tool exist and base their judgement on their feelings...).



For companion example let us consider the following list of data:

	A	B	C	D
1	**#Event of interest observed**	**Number of items manufactured until event**	**UCL**	**LCL**
2	1	1500	12214.98	33.45
3	2	166	12214.98	33.45
4	3	2501	12214.98	33.45
5	4	238	12214.98	33.45
6	5	1392	12214.98	33.45
7	6	4686	12214.98	33.45
8	7	128	12214.98	33.45
9	8	31	12214.98	33.45
10	9	2566	12214.98	33.45
11	10	591	12214.98	33.45
12	11	470	12214.98	33.45
13	12	502	12214.98	33.45
14	13	4147	12214.98	33.45
15	14	1131	12214.98	33.45
16	15	884	12214.98	33.45
17	16	1864	12214.98	33.45
18	17	665	12214.98	33.45
19	18	3364	12214.98	33.45
20	19	881	12214.98	33.45
21	20	4726	12214.98	33.45
22	21	517	12214.98	33.45
23	22	5787	12214.98	33.45
24	23	1250	12214.98	33.45
25	24	2869	12214.98	33.45
26	25	7087	12214.98	33.45
27	26	18653	12214.98	33.45
28	27	7772	12214.98	33.45
29	28	1683	12214.98	33.45

Which gives graphically:



Well it's nice, but we need an UCL and LCL for this control chart to be really useful! To achieve this we will use the queuing theory with the same assumptions and the same checkpoints (see section Quantitative Management page 8141). Let us first recall that we had showed there that the probability of observing k events in a time interval t (or an interval of pieces number t) under some very specific assumptions (!!!), followed a Poisson distribution:

$$p_k \cong \frac{(\lambda t)^k}{k!} e^{-\lambda t} \qquad (16.7.883)$$

where the parameter λ is the average arrival rate (or "average rate of occurrence") of events per unit time (or "Poisson Arrivals See Time Average (PASTA)") assumed constant over the entire period:

$$\lambda = \frac{1}{\overline{\overline{T}}} \qquad (16.7.884)$$

and where we have for mean and variance (see section Statistics page 686) the number of events:

$$\text{E}(k) = \lambda t \qquad \text{V}(k) = \lambda t \qquad (16.7.885)$$

This is a probability law with discreet support as we know, which fits well with our case studies so the Poisson distribution can be a good candidate (but there are others, like for example the Geometric law!!!).

But we also proved that the random variable τ representing the time (or the number of pieces) separating two arrivals of unwanted events (or desired...) was given by the distribution function based on the exponential law:

$$A(\tau \leq t) = 1 - e^{-\lambda t} \qquad (16.7.886)$$

Still with:

$$\lambda = \frac{1}{\overline{\overline{T}}} \qquad (16.7.887)$$

where:

$$\mu = \sigma = \frac{1}{\lambda} = \overline{T} \qquad (16.7.888)$$

So we could take the following Shewhart limits :

$$\boxed{\begin{aligned} \text{USL} &= \text{required by customer/board comitee} \\ \text{UCL}_T &= \overline{T} + 3\overline{T} \\ \text{CL}_T &= \text{E}(k) = \overline{T} \\ \text{LCL}_T &= \overline{T} - 3\overline{T} := 0 \end{aligned}} \qquad (16.7.889)$$

But it is more rigorous (as for all other control charts) to use probabilistic limits. So if we want to set limits with a usual bilateral risk threshold $\alpha/2$ of 0.5% then we calculate for the lower limit:

$$\frac{\alpha}{2} = 1 - e^{-\lambda x} \Rightarrow x = \frac{\ln\left(1 - \dfrac{\alpha}{2}\right)}{-\lambda} = -\ln\left(1 - \frac{0.25\%}{2}\right)\overline{T} \cong 0.012\overline{T} \qquad (16.7.890)$$

and for the superior limit:

$$1-\frac{\alpha}{2}=1-e^{-\lambda x}\Rightarrow x=\frac{\ln\left(\frac{\alpha}{2}\right)}{-\lambda}=-\ln\left(\frac{0.25\%}{2}\right)\overline{T}\cong 4.382\overline{T} \tag{16.7.891}$$

Then we have:

	A	B	C	D	E
1	#Event of interest observed	Number of items manufactured until event	Average	UCL	LCL
2	1	1500	2787.536	12214.98	33.45
3	2	166	2787.536	12214.98	33.45
4	3	2501	2787.536	12214.98	33.45
5	4	238	2787.536	12214.98	33.45
6	5	1392	2787.536	12214.98	33.45
7	6	4686	2787.536	12214.98	33.45
8	7	128	2787.536	12214.98	33.45
9	8	31	2787.536	12214.98	33.45
10	9	2566	2787.536	12214.98	33.45
11	10	591	2787.536	12214.98	33.45
12	11	470	2787.536	12214.98	33.45
13	12	502	2787.536	12214.98	33.45
14	13	4147	2787.536	12214.98	33.45
15	14	1131	2787.536	12214.98	33.45
16	15	884	2787.536	12214.98	33.45
17	16	1864	2787.536	12214.98	33.45
18	17	665	2787.536	12214.98	33.45
19	18	3364	2787.536	12214.98	33.45
20	19	881	2787.536	12214.98	33.45
21	20	4726	2787.536	12214.98	33.45
22	21	517	2787.536	12214.98	33.45
23	22	5787	2787.536	12214.98	33.45
24	23	1250	2787.536	12214.98	33.45
25	24	2869	2787.536	12214.98	33.45
26	25	7087	2787.536	12214.98	33.45
27	26	18653	2787.536	12214.98	33.45
28	27	7772	2787.536	12214.98	33.45
29	28	1683	2787.536	12214.98	33.45

Thus explicitly:

	A	B	C	D	E
1	#Event of interest observed	Number of items manufactured until event	Average	UCL	LCL
2	1	1500	=AVERAGE($B$2:$B$29)	=4.382*AVERAGE($B$2:$B$29)	=0.012*AVERAGE($B$2:$B$29)
3	2	166	=AVERAGE($B$2:$B$29)	=4.382*AVERAGE($B$2:$B$29)	=0.012*AVERAGE($B$2:$B$29)

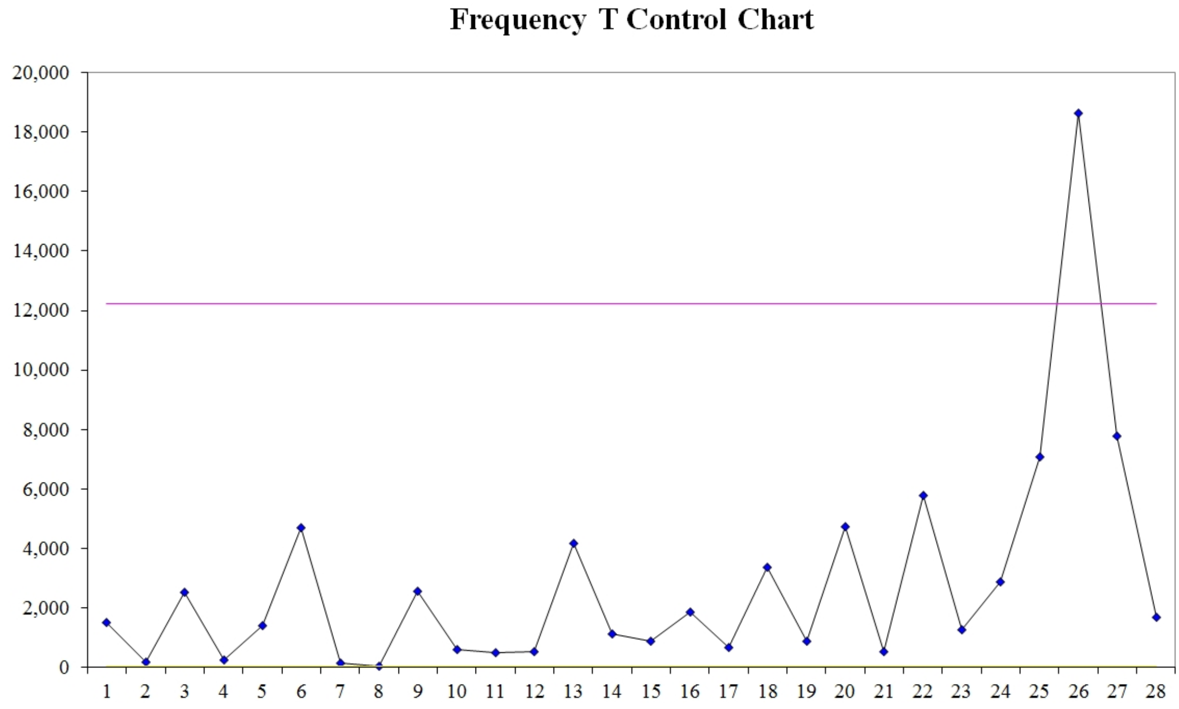
7	6	4686	=AVERAGE($B$2:$B$29)	=4.382*AVERAGE($B$2:$B$29)	=0.012*AVERAGE($B$2:$B$29)
8	7	128	=AVERAGE($B$2:$B$29)	=4.382*AVERAGE($B$2:$B$29)	=0.012*AVERAGE($B$2:$B$29)
9	8	31	=AVERAGE($B$2:$B$29)	=4.382*AVERAGE($B$2:$B$29)	=0.012*AVERAGE($B$2:$B$29)
10	9	2566	=AVERAGE($B$2:$B$29)	=4.382*AVERAGE($B$2:$B$29)	=0.012*AVERAGE($B$2:$B$29)
11	10	591	=AVERAGE($B$2:$B$29)	=4.382*AVERAGE($B$2:$B$29)	=0.012*AVERAGE($B$2:$B$29)
12	11	470	=AVERAGE($B$2:$B$29)	=4.382*AVERAGE($B$2:$B$29)	=0.012*AVERAGE($B$2:$B$29)
13	12	502	=AVERAGE($B$2:$B$29)	=4.382*AVERAGE($B$2:$B$29)	=0.012*AVERAGE($B$2:$B$29)
14	13	4147	=AVERAGE($B$2:$B$29)	=4.382*AVERAGE($B$2:$B$29)	=0.012*AVERAGE($B$2:$B$29)
15	14	1131	=AVERAGE($B$2:$B$29)	=4.382*AVERAGE($B$2:$B$29)	=0.012*AVERAGE($B$2:$B$29)
16	15	884	=AVERAGE($B$2:$B$29)	=4.382*AVERAGE($B$2:$B$29)	=0.012*AVERAGE($B$2:$B$29)
17	16	1864	=AVERAGE($B$2:$B$29)	=4.382*AVERAGE($B$2:$B$29)	=0.012*AVERAGE($B$2:$B$29)
18	17	665	=AVERAGE($B$2:$B$29)	=4.382*AVERAGE($B$2:$B$29)	=0.012*AVERAGE($B$2:$B$29)
19	18	3364	=AVERAGE($B$2:$B$29)	=4.382*AVERAGE($B$2:$B$29)	=0.012*AVERAGE($B$2:$B$29)
20	19	881	=AVERAGE($B$2:$B$29)	=4.382*AVERAGE($B$2:$B$29)	=0.012*AVERAGE($B$2:$B$29)
21	20	4726	=AVERAGE($B$2:$B$29)	=4.382*AVERAGE($B$2:$B$29)	=0.012*AVERAGE($B$2:$B$29)
22	21	517	=AVERAGE($B$2:$B$29)	=4.382*AVERAGE($B$2:$B$29)	=0.012*AVERAGE($B$2:$B$29)
23	22	5787	=AVERAGE($B$2:$B$29)	=4.382*AVERAGE($B$2:$B$29)	=0.012*AVERAGE($B$2:$B$29)
24	23	1250	=AVERAGE($B$2:$B$29)	=4.382*AVERAGE($B$2:$B$29)	=0.012*AVERAGE($B$2:$B$29)
25	24	2869	=AVERAGE($B$2:$B$29)	=4.382*AVERAGE($B$2:$B$29)	=0.012*AVERAGE($B$2:$B$29)
26	25	7087	=AVERAGE($B$2:$B$29)	=4.382*AVERAGE($B$2:$B$29)	=0.012*AVERAGE($B$2:$B$29)
27	26	18653	=AVERAGE($B$2:$B$29)	=4.382*AVERAGE($B$2:$B$29)	=0.012*AVERAGE($B$2:$B$29)
28	27	7772	=AVERAGE($B$2:$B$29)	=4.382*AVERAGE($B$2:$B$29)	=0.012*AVERAGE($B$2:$B$29)
29	28	1683	=AVERAGE($B$2:$B$29)	=4.382*AVERAGE($B$2:$B$29)	=0.012*AVERAGE($B$2:$B$29)

We then have the following control chart (we have exceptionally not represented the USL on it):



With Minitab 17.3.1 we get something quite different for all control limits. As the Minitab team doesn't give the proofs but only the formulas we are not able to say who has the most correct way between us and them for these calculations:

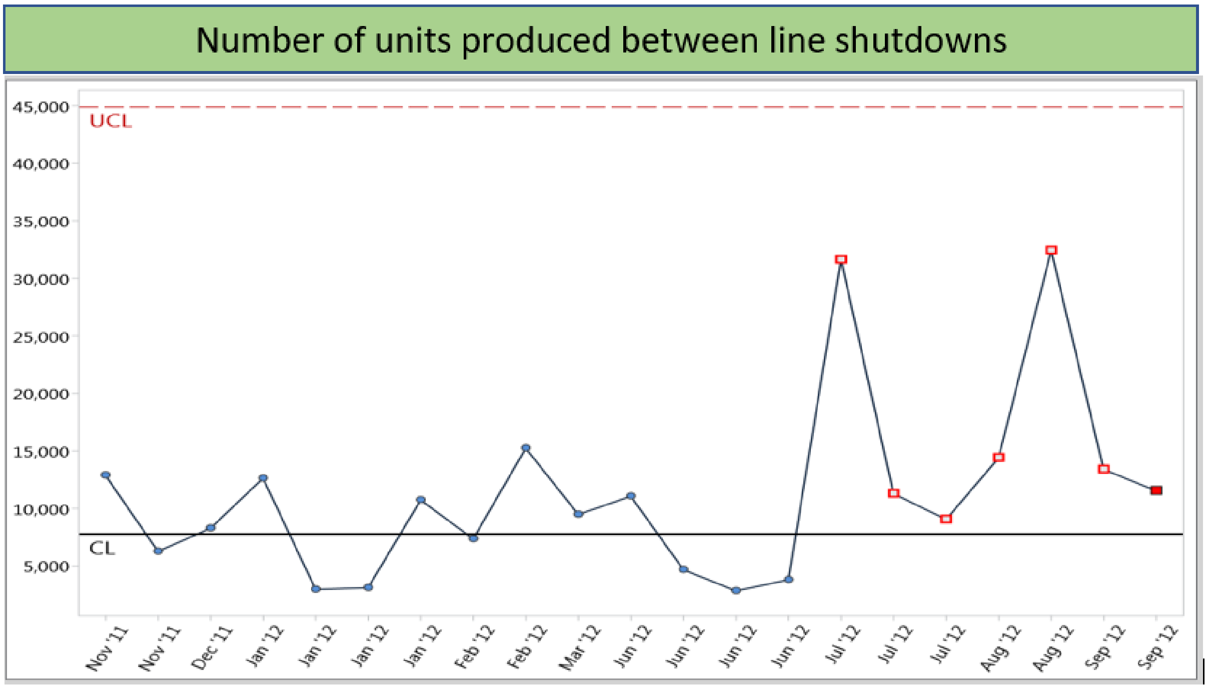
Observation

At least one estimated historical parameter is used in the calculations.

16.7.6.6.2 Frequency G control chart of rare events

Developed by James Benneyan in 11991 (holocene calendar), the G chart[38] is a control chart that is based on the geometric distribution. Benneyan has since published several papers about the G chart and a companion chart, the "h chart". The majority of applications cited in these papers are for monitoring infection rates in healthcare, such as nosocomial infections. Nosocomial infections are infections that occur as a direct result of a patient's treatment in a medical facility.

P charts and U charts are often used to monitor adverse events such as nosocomial infections. But P charts and U charts require very large quantities of data and specific definitions of the data. For example, if you use a U chart to monitor nosocomial infections, each patient day is considered an area of opportunity in which one or more infections could occur. Thus, the data are the number of infections per patient day. If you use a P chart, the data are the number of patient days in which one or more infections occur. As for the data requirements, if you follow the standard practice of requiring a minimum of 25 to 35 subgroups to establish control limits, and the infection rate is low (for example, $< 1\%$), the required amount of data is at least $12,500$ patients (500 patients per subgroup multiplied by 25 subgroups). This means that it could take weeks, months, or perhaps even years to accumulate enough data to detect and respond to changes in the infection rate.



The geometric distribution provides an alternative probability model. In the geometric distribution, you count the number of opportunities before or until the defect occurs. Thus, in a healthcare setting where you monitor the infection rate, the ideal would be to count the number of patients or procedures until an infection is observed. While this is the ideal, it is also rarely done, because of complications with counting the actual number of patients through the system, or the number of procedures. What is most often done is to count the number of days between observed infections. The key assumption used when counting the number of days is that the number of patients or procedures per day is fairly constant.

---

[38] The "G" in G Chart stands for "geometric" because the number of normal events between nonconforming or rare incidents is represented by a geometric distribution.

We have proved in the section Statistics (see page 667) that the mean to have R successes before the E-th failure knowing that the probability of a failure is p was given by the mean of the negative binomial distribution:

$$\text{E}(R)=\frac{E}{p}\tag{16.7.892}$$

and we get for to the variance:

$$\text{V}(R)=E\frac{q}{p^2}\tag{16.7.893}$$

Obviously, if we set E as the first failure, the mean is reduced to that of the geometric law:

$$\text{E}(R)=\frac{1}{p}\qquad\text{and}\qquad\text{E}(V)=\frac{q}{p^2}=\frac{1-p}{p^2}\tag{16.7.894}$$

We have proved in the section Statistics (see page 654) that the estimator of the parameter of the geometric law was given by:

$$\hat{p}=\frac{k}{N}\tag{16.7.895}$$

Therefore it comes:

$$\text{E}(R)=\frac{N}{k}=\overline{g}\tag{16.7.896}$$

and:

$$\text{V}(R)=\frac{1-\left(\dfrac{k}{N}\right)}{\left(\dfrac{k}{N}\right)^2}=\left(\frac{N}{k}\right)^2\left(1-\left(\frac{k}{N}\right)\right)=\left(\frac{N}{k}\right)^2-\frac{N}{k}=\frac{N}{k}\left(\frac{N}{k}-1\right)=\overline{g}\left(\overline{g}-1\right)\tag{16.7.897}$$

and therefore:

$$\hat{\sigma}_R=\sqrt{\overline{g}(\overline{g}-1)}\tag{16.7.898}$$

Therefore we have:

$$\boxed{\begin{aligned}\text{USL}&=\text{required by customer/board comitee}\\ \text{UCL}_G&=\overline{g}+3\sqrt{\overline{g}\left(\overline{g}-1\right)}\\ \text{CL}_G&=\overline{g}\\ \text{LCL}_G&=\overline{g}-3\sqrt{\overline{g}\left(\overline{g}-1\right)}\end{aligned}}\tag{16.7.899}$$

where if LCL is negative, we put it as always as being equal to zero.

Let us see an example by considering the following list in Microsoft® Excel® 14.0.6123:

	A	B	C	D	E
1	**Date**	**Days Between events**	**g**	**LCL**	**UCL**
2	2009-02-05		39.24	0	155.43

17
Observation

For a software like Minitab, the lower control limit of the rare events chart is set to the percentile 0.0013499 of the geometric distribution (taking the nearest decimal value by linear interpolation). The upper control limit is set to the percentile 0.99865 (also taking the nearest decimal value by linear interpolation). The central line is set at 0.5 percentile (taking the nearest decimal value by linear interpolation).

It should be also remembered that the Geometric law (or the Negative Binomial law) is not necessarily symmetrical! This is why, in practice, you should rather use the median for the CL (centerline which can be determined by simple simulations of the law and taking the nearest value of the 50% percentile) and for the LCL and UCL control limits use also the probabilistic simulations.

16.7.6.7 Control Charts Operating Characteristic (OC) Curves

In the usage of control charts we face two types of errors (putting apart human error and incompetence error...) that are well known to us in the context of our study of statistics:

- Type I error: We detect an alarm when there is actually no alarm
- Type II error: We are out of control but we do not detect alarm

The aim here will be to determine the conditions for controlling these two errors.

As we will see the operating characteristic function for a Shewhart chart givens the probability that the statistic of interest falls between the lower and upper control limits.

16.7.6.7.1 OC for $\bar{X}$ measurement control charts

We have already proved earlier above that the capability that a centered process taken at a distance of 3σ had a cumulative probability of 0.27% $(1/370)$ to have a point outside the 3σ and this only for reasons of statistical fluctuations (error of Type I)! So in extenso to 3σ the error type II is $1-0.27\%$ which is quite huge but acceptable in practice (as practitioner consider a power of 80% as being acceptable)! The reason for this high amplitude of type II error is implicitly due to the fact that we calculate here:

$$\beta=P(\text{LSL}\leq\bar{X}\leq\text{USL}|\mu_{\bar{X}}=0,\sigma_{\bar{X}}=1)=\Phi(\text{USL})-\Phi(\text{LSL}) \tag{16.7.900}$$

that is to say that the data have all been centered reduced as well as in extenso that the USL and the LSL and where for recall is the symbol Φ stand for the cumulative probability function of the Normal law $\mathcal{N}(0,1)$.

But if the data is not centered, then we must calculate:

$$\beta=P\left(\text{LSL}\leq\bar{X}\leq\text{USL}|\mu_{\bar{X}}=\bar{X},\sigma_{\bar{X}}=\frac{\sigma_X}{\sqrt{n}}\right)=\Phi\left(\frac{\text{USL}-\bar{X}}{\frac{\sigma_X}{\sqrt{n}}}\right)-\Phi\left(\frac{\text{LSL}-\bar{X}}{\frac{\sigma_X}{\sqrt{n}}}\right) \tag{16.7.901}$$

But if we are interested in a certain lag by loss of control of the process, then we have by expressing these shifts in multiples m of σ_X as it is done by tradition (this choice will be justified a little later):

$$\begin{aligned}\beta&=P\left(\text{LSL}\leq\bar{X}\leq\text{USL}|\mu_{\bar{X}}=\bar{X}+m\sigma_{\bar{X}},\sigma_{\bar{X}}=\frac{\sigma_X}{\sqrt{n}}\right)\\&=\Phi\left(\frac{\text{USL}-(\bar{X}+m\sigma_X)}{\frac{\sigma_X}{\sqrt{n}}}\right)-\Phi\left(\frac{\text{LSL}-(\bar{X}+m\sigma_X)}{\frac{\sigma_X}{\sqrt{n}}}\right)\end{aligned} \tag{16.7.902}$$

Now, let us recall that we have in the framework of a $\bar{X}$ control chart:

$$\begin{aligned}\text{USL} &= \bar{X} + k\sigma_{\bar{X}} \\ \text{LSL} &= \bar{X} - k\sigma_{\bar{X}}\end{aligned} \tag{16.7.903}$$

Therefore it comes:

$$\begin{aligned}\beta &= \Phi\left(\frac{(\bar{X}+k\sigma_{\bar{X}})-(\bar{X}+m\sigma_X)}{\frac{\sigma_X}{\sqrt{n}}}\right) - \Phi\left(\frac{(\bar{X}-k\sigma_{\bar{X}})-(\bar{X}+m\sigma_X)}{\frac{\sigma_X}{\sqrt{n}}}\right) \\ &= \Phi\left(\frac{k\sigma_{\bar{X}}-m\sigma_X}{\frac{\sigma_X}{\sqrt{n}}}\right) - \Phi\left(\frac{-k\sigma_{\bar{X}}-m\sigma_X}{\frac{\sigma_X}{\sqrt{n}}}\right) = \Phi\left(\frac{k\frac{\sigma_X}{\sqrt{n}}-m\sigma_X}{\frac{\sigma_X}{\sqrt{n}}}\right) - \Phi\left(\frac{-k\frac{\sigma_X}{\sqrt{n}}-m\sigma_X}{\frac{\sigma_X}{\sqrt{n}}}\right) \\ &= \Phi(k-m\sqrt{n}) - \Phi(-k-m\sqrt{n})\end{aligned} \tag{16.7.904}$$

We see that the choices at the beginning in the way of noting the offset advantage us by the fact that the error of type II is a function of more than three parameters of which k is almost always fixed at 3 and n is chosen by the experimenter.

So finally we have:

$$\boxed{\beta(m) = \Phi(k-m\sqrt{n}) - \Phi(-k-m\sqrt{n})} \tag{16.7.905}$$

✍**Example:**

Suppose we use a $\bar{X}$ control chart with a k of $3\sigma_{\bar{X}}$, a sample size of $n=5$ and we want to know the Type II error to detect an offset of $2\sigma_X$ $(m=2)$. From then on, it comes:

$$\beta(m) = \Phi(3-2\sqrt{5}) - \Phi(-3-2\sqrt{5}) \cong 0.0705 = 7.05\% \tag{16.7.906}$$

So the risk of type II is this time much lower but the error of type I then becomes $1-0.0705=0.9295$ which is huge. This is why it is often necessary to find the right compromise between the quality policy and the adjustment costs.

Let us indicate that the general case, for k equal to 3, we have the following curve which is named "$\bar{X}$ control chart operating characteristic curve":

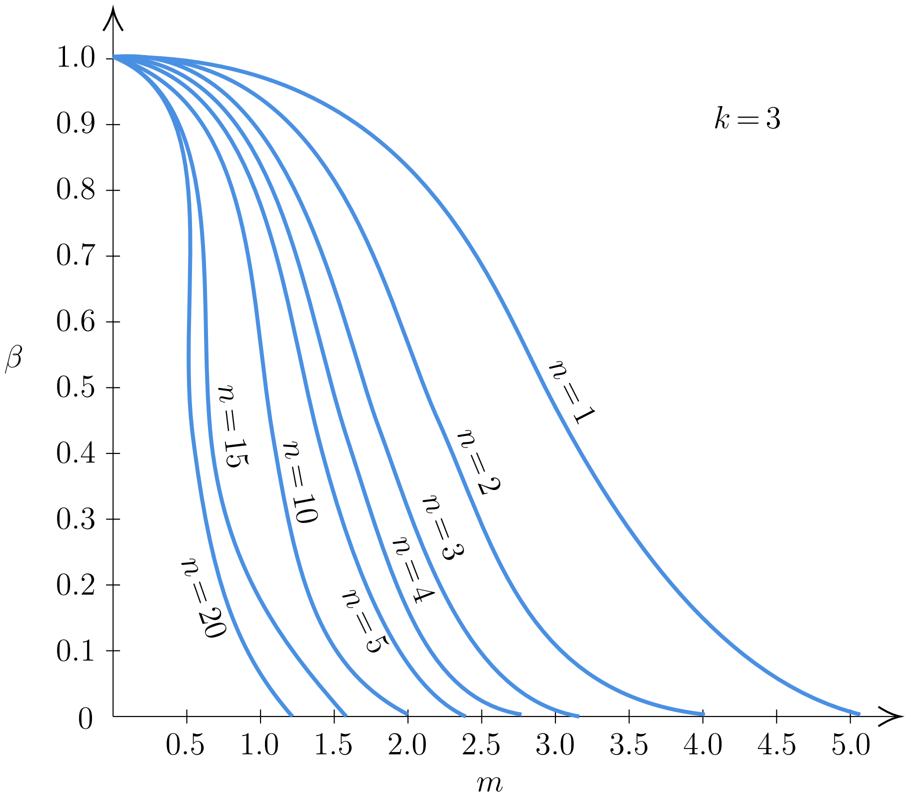

Figure 16.286: $\bar{X}$ **control chart operating characteristic curve**

So on the plot above we have $k=3$, $n=5$, $m=2$:

$$\beta(2)=\Phi(k-m\sqrt{n})-\Phi(-k-m\sqrt{n})=\Phi(3-2\sqrt{5})-\Phi(-3-2\sqrt{5})\cong 0.07 \tag{16.7.907}$$

either with the English version of Microsoft® Excel® 14.0.7177:

```
=NORM.S.DIST(3-2*SQRT(5),TRUE)-NORM.S.DIST(-3-2*SQRT (5),TRUE)
```

16.7.6.7.2 OC for P-type attribute control charts

The same type of reasoning applies for an attributes P-type control chart! We have then:

$$\beta=P(\text{LSL}\leq\hat{p}\leq\text{USL}|n,p)=\mathcal{B}\left(\bar{\hat{p}}+k\sqrt{\frac{\bar{\hat{p}}(1-\bar{\hat{p}})}{N}},n,\bar{\hat{p}}\right)-\mathcal{B}\left(\bar{\hat{p}}-k\sqrt{\frac{\bar{\hat{p}}(1-\bar{\hat{p}})}{N}}n,\bar{\hat{p}}\right) \tag{16.7.908}$$

However, we saw in the Statistics section (see page 872) that when N is large the interval could be estimated using a Normal law such that:

$$\hat{p}-Z_{\alpha/2}\sqrt{\frac{\hat{p}(1-\hat{p})}{n}}\leq p\leq\hat{p}+Z_{\alpha/2}\sqrt{\frac{\hat{p}(1-\hat{p})}{n}} \tag{16.7.909}$$

Hence, since $\bar{\hat{p}}$ follow approximately a Normal law, we arrive at the same type of calculations as for the previous control chart:

$$\begin{aligned}\beta &= P\left(\text{LSL} \leq \bar{\hat{p}} \leq \text{USL} | p = \bar{\hat{p}}, \sigma = \sqrt{\frac{\bar{\hat{p}}(1-\bar{\hat{p}})}{N}}\right)\\ &= \Phi\left(\frac{\text{USL}-\bar{\hat{p}}}{\sqrt{\dfrac{\bar{\hat{p}}(1-\bar{\hat{p}})}{N}}}\right) - \Phi\left(\frac{\text{LSL}-\bar{\hat{p}}}{\sqrt{\dfrac{\bar{\hat{p}}(1-\bar{\hat{p}})}{N}}}\right)\end{aligned} \tag{16.7.910}$$

Thus finally:

$$\boxed{\beta = \Phi\left(\frac{\text{USL}-\bar{\hat{p}}}{\sqrt{\dfrac{\bar{\hat{p}}(1-\bar{\hat{p}})}{N}}}\right) - \Phi\left(\frac{\text{LSL}-\bar{\hat{p}}}{\sqrt{\dfrac{\bar{\hat{p}}(1-\bar{\hat{p}})}{N}}}\right)} \tag{16.7.911}$$

16.7.7 Design of reliability tests

"Reliability test plans" have two main functions: One is to determine the sample size and testing time needed to estimate model parameters. The other is to demonstrate that we have met specified reliability requirements.

A test plan includes:

- The number of units you need to test.
- A stopping rule: the amount of time you must test each unit or the number of failures that must occur.
- Success criterion: the number of failures allowed while the test still passes (for example, all units are tested for the specified amount of time and there are no failures).

Three types of test plans are available: demonstration, estimation, and accelerated life.

Definitions (#16.7.740):

D1. "Demonstration plan" to determine the sample size or testing time needed to demonstrate, with some level of confidence, that the reliability is higher than a particular standard.

There are two types of demonstration tests:

1. "Substantiation tests" that provide statistical evidence that a redesigned system suppressed or significantly reduced a known cause of failure. For example, is the redesigned system better than the previous system?

   We can rewrite these hypotheses in terms of the scale (Weibull or exponential distribution) or location Reliability test (other distributions), a percentile, the reliability at a particular time, or the mean time to failure (MTTF). For example, we can test whether the MTTF for a redesigned system is greater than the MTTF for the previous system.

2. "Reliability test" that provide statistical evidence that a reliability specification is achieved. For example, is the system reliability greater than a goal value?

D2. "Estimation test plans" to determine the number of test units that we need to estimate percentiles or reliabilities with a specified degree of precision. Estimation test plans are similar to classic sample-size problems, but computations are more intensive because the data are usually censored.

D3. "Accelerated life test plans" to determine - under some very strong assumptions - the number of units to test and the allocation of those test units across stress levels for an accelerated life test. We can also use these test plans to determine the standard error for the parameter we want to estimate for a fixed number of test unit

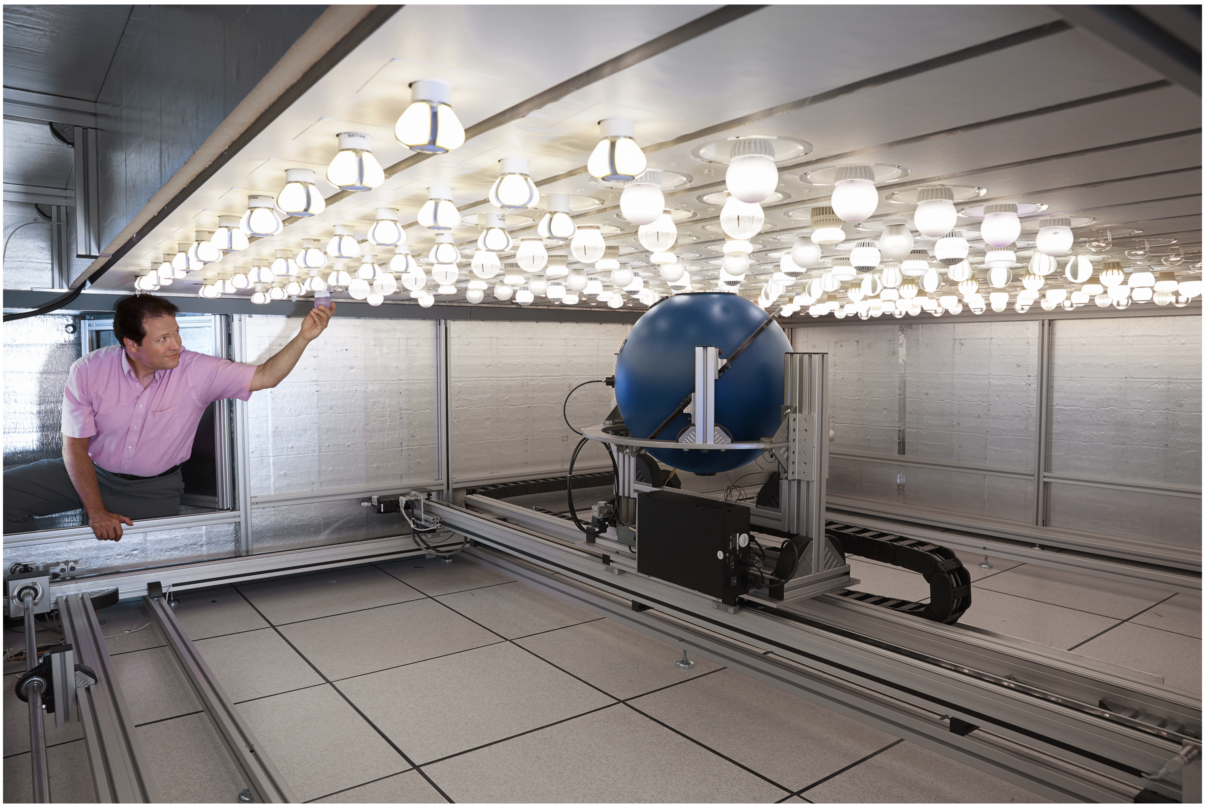

Figure 16.287: **Pacific Northwest National Laboratory automatic long-term performance measurement equipment for Philips LED 60 Watt, which can test up to 200 lamps at a time**

Several methods have been designed to help engineers for all this purposes: Cumulative Binomial, Nonparametric Binomial, Exponential Chi-Squared and Nonparametric Bayesian. They are discussed in the following paragraphs.

16.7.7.1 Chi-squared time of test

A method for designing tests for products that have an assumed constant failure rate, or exponential life distribution, draws on the chi-squared distribution. This method only returns the necessary accumulated test time for a demonstrated reliability or $\overline{\text{MTTF}}$ (or for not repairable items for the $\overline{\text{MTBF}}$ obviously!).

We have seen earlier above that for a survival function of the form:

$$R(t)=e^{-\lambda t} \tag{16.7.912}$$

The corresponding density function was the exponential law:

$$f(t)=\lambda e^{-\lambda t} \tag{16.7.913}$$

and that we had (also valid for the MTBF):

$$\text{MTTF}=\frac{1}{\mu} \tag{16.7.914}$$

Our objective here will be to find the value that permits a reliability engineer to know how long a test must be performed to demonstrate with a 90% confidence level (CL) that its product has zero failure.

What looks like in the worldwide reference Weibull++ software for reliability engineering as following:

Exponential assumption implies a constant failure rate

Result

Accumulated Test Time Required 230.2586

Figure 16.288: Exponential Chi-squares time test in Weibull++ 7 software

We will prove in the following that this result follows from a close relationship between the exponential distribution, the Poisson distribution through the queue theory (see section Quantitative Management page 8141) and the chi-square distribution.

To prove this result, let us recall that we have prove in the section of Quantitative Management that under certain hypotheses of a queue, the probability of seeing an event in an interval of duration t is given by the function:

$$p_k \cong \frac{(\lambda t)^k}{k!}e^{-\lambda t} \tag{16.7.915}$$

and that the corresponding density function of the corresponding time between two events is an exponential law. In other words, when the time of failure follows an exponential law, the probability of a certain number of failures in a certain time interval follows the relation given just before!

The previous relation can be used in the case of reliability to obtain an upper bound of λ for a given time interval t since we can then write with the Erlang distribution function (see section Quantitative Management page 8147):

$$F(t,k)=1-\text{CL}=\sum_{k=0}^{f}\frac{(\lambda t)^k}{k!}e^{-\lambda t} \tag{16.7.916}$$

A small and simple change of variable gives:

$$1-\text{CL}=\sum_{k=0}^{f}\frac{x^k}{k!}e^{-x} \tag{16.7.917}$$

We therefore recognize the Poisson distribution! However, this is impossible to reverse by hand (as far as we know). Reason why it is wiser to find a relation with another known distribution that is continuous in the purpose to reverse it by hand.

For this, let us recall that we have proved during our study of the chi-square law in the section Statistics (see page 773) that:

$$\sum_{k=0}^{n-1}\frac{\lambda^k}{k!}e^{-\lambda}=1-\int_0^{\lambda}\frac{1}{2^{k/2}\Gamma(k/2)}x^{k/2-1}e^{-x/2}\mathrm{d}x \tag{16.7.918}$$

Therefore, by re-reading carefully the changes of variables made in the section Statistics we have in other words:

$$\sum_{k=0}^{n-1}\frac{\lambda^k}{k!}e^{-\lambda}=1-\chi_k^2(x\leq 2\lambda)=1-\chi_{2n}^2(x\leq 2\lambda) \tag{16.7.919}$$

It is therefore immediate that:

$$1-\mathrm{CL}=1-\sum_{k=0}^{f}\frac{(\lambda t)^k}{k!}e^{-\lambda t}=1-\chi_{2(f+1)}^2(x\leq 2\lambda t) \tag{16.7.920}$$

It follows that:

$$\mathrm{CL}=1-\sum_{k=0}^{f}\frac{x^k}{k!}e^{-x}=x_{2(f+1)}^2(2\lambda t) \tag{16.7.921}$$

Conversely:

$$\chi_{\mathrm{CL},2(f+1)}^2=2\lambda t=\frac{2t}{\mathrm{MTTF}} \tag{16.7.922}$$

Therefore:

$$\boxed{t=\frac{\mathrm{MTTF}\chi_{\mathrm{CL},2(f+1)}^2}{2}} \tag{16.7.923}$$

16.7.7.2 Binomial sampling size

In demonstration plans, an important calculation is to determine the size of a sample in order to demonstrate a certain degree of reliability for a given level of confidence. In the case where the test time is equal to the demonstration time, the binomial distribution is widely used in practice because nonparametric and we need only to have the knowledge of the estimated parameter R (see earlier above):

$$\boxed{1-\text{CL}=\sum_{i=0}^{f}\binom{n}{i}(1-R)^i R^{n-i}=\sum_{i=0}^{f}\frac{n!}{i!(n-i)!}(1-R)^i R^{n-i}} \quad (16.7.924)$$

with f the number of failures, n the size of the sample, and R the reliability that is sought to be demonstrated. We then speak of a "nonparametric binomial demonstration plan" or simply sometimes of "nonparametric zero failure".

As the reader may have noticed it, there is no time value associated with this methodology, so one must assume that the value of R is associated with the amount of time for which the units were tested.

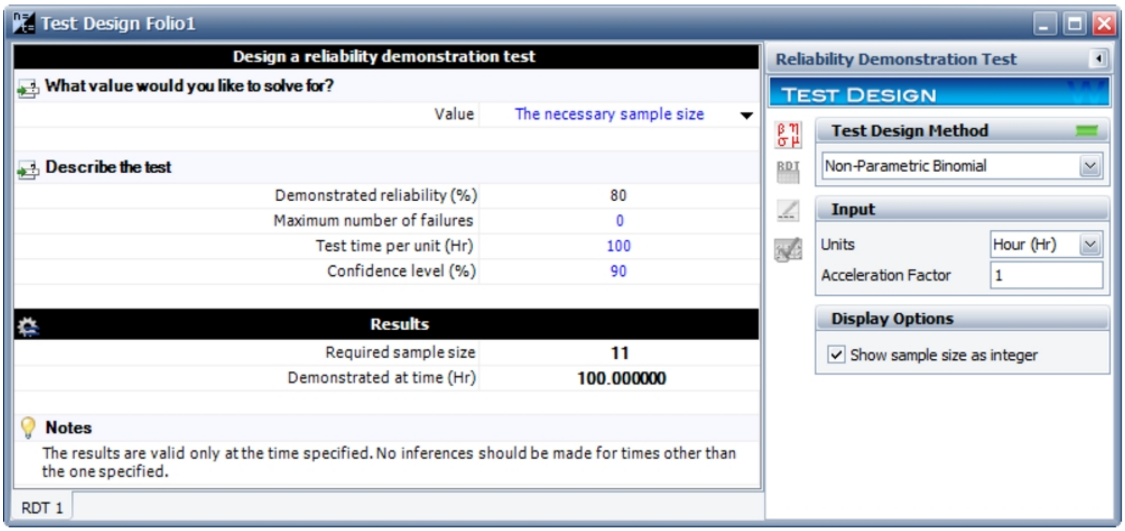
✍**Example:**

Consider that an engineer wants to set up a demonstration plan in order to demonstrate the zero failure of a product with an 80% reliability with a confidence level of 90%. We have then:

$$1-90\%=10\%=\sum_{i=0}^{0}\binom{n}{i}(1-R)^iR^{N-i}=R^N=0.80^N \qquad (16.7.925)$$

This gives by taking the logarithm:

$$N=\frac{\log(0.1)}{\log(0.80)}=10.31\cong 11 \qquad (16.7.926)$$



Design a reliability demonstration test

What value would you like to solve for?

Acceleration Factor	1

Display Options

☑ Show sample size as integer

Figure 16.289: Binomial sample size demonstration plan in Weibull++ 7 software

However, in reliability tests, in order to better estimate reliability, Bayesian methods are used, especially when sample size is financially limited. If there is an a priori information about the reliability of the system, this information can then be used to build better demonstration plans.

We will see later that the application of Bayesian techniques gives a quasi-similar result to the above example for certain values a priori well chosen...

We can involve also the reliability indirectly with a reliability function. For this, let us consider the following example:

✍**Example:**

We want to design a test to demonstrate a reliability of 90% at $t_{\text{demo}}=100$ hours with a 95% confidence if no failure occur during the test. We will assume a Weibull distribution with a shape parameter $\beta=1.5$ and we know that we have the testing facilities available for $t=48$ hours.

We must now determine the number of units to test for this amount of time with no failures in order to have demonstrated our reliability goal. The first step is to determine the Weibull scale parameter, η. The Weibull reliability equation is:

$$R = e^{-(t/\eta)^{\beta}} \tag{16.7.927}$$

This can be rewritten as:

$$\eta = \frac{t_{\text{demo}}}{(-\ln(R_{\text{demo}})^{\frac{1}{\beta}}} \tag{16.7.928}$$

Since we know the values of t_{demo}, R_{demo} and β, we can substitute these in the equation and solve for η:

$$\eta = \frac{100}{-\ln(0.9)^{\frac{1}{1.5}}} = 448.3 \tag{16.7.929}$$

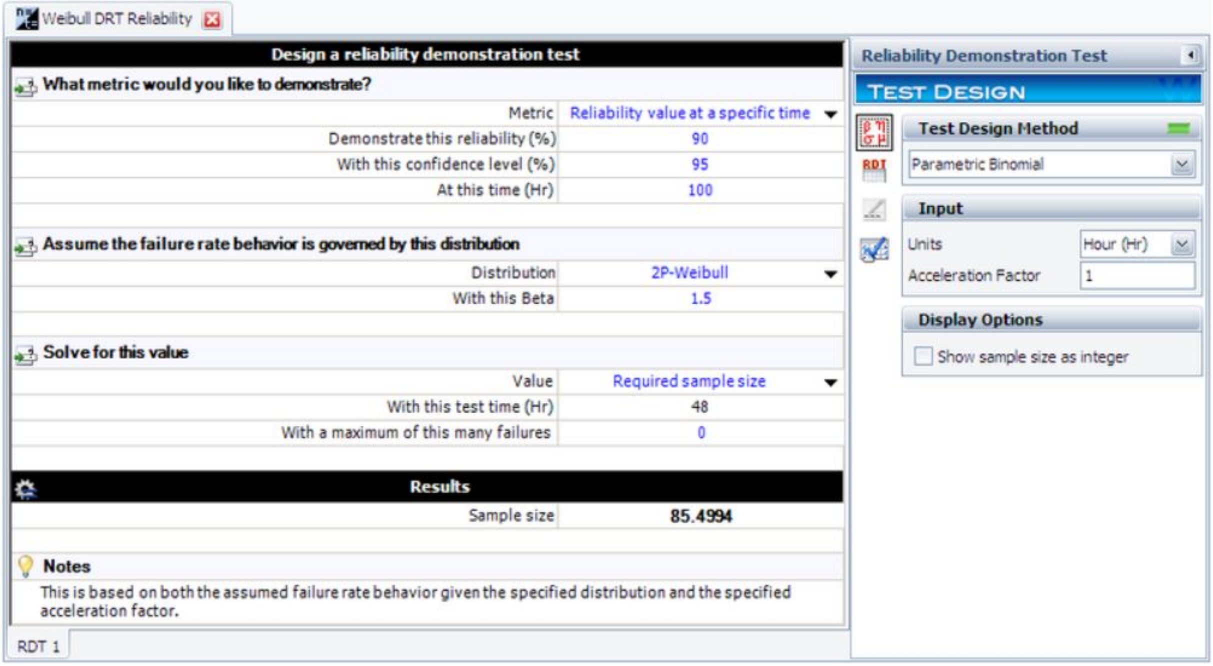
Next the value of R_{test} is calculated by:

$$R_{\text{test}} = e^{-(t_{\text{test}}/\eta)^{\beta}} = e^{-(48/448.3)^{1.5}} = 0.966 = 96.6\% \tag{16.7.930}$$

The last step is to substitute the appropriate values into the cumulative binomial equation, which for the Weibull distribution appears as:

$$1-\text{CL} = \sum_{i=0}^{f} \frac{n!}{i!(n-i)!} \cdot \left(1 - e^{-(t_{\text{test}}/\eta)^{\beta}}\right)^{i} \cdot \left(e^{-(t_{\text{test}}/\eta)^{\beta}}\right)^{(n-i)} \tag{16.7.931}$$

The values of CL, t_{test}, β, f and η have already been calculated or specified, so it merely remains to solve the equation for n. This value is $n = 85.4994$, or $n = 86$ units, since the fractional value must be rounded up to the next integer value. This example solved in Weibull++ is shown next.



Design a reliability demonstration test

What metric would you like to demonstrate?

Metric	Reliability value at a specific time
Demonstrate this reliability (%)	90
With this confidence level (%)	95
At this time (Hr)	100

Assume the failure rate behavior is governed by this distribution

Distribution	2P-Weibull
With this Beta	1.5

Solve for this value

Value	Required sample size
With this test time (Hr)	48
With a maximum of this many failures	0

Results

Sample size	85.4994

Notes

This is based on both the assumed failure rate behavior given the specified distribution and the specified acceleration factor.

Test Design Method: Parametric Binomial

Units: Hour (Hr)

Acceleration Factor: 1

☐ Show sample size as integer

Figure 16.290: **Weibull reliability sample size with Weibull++**

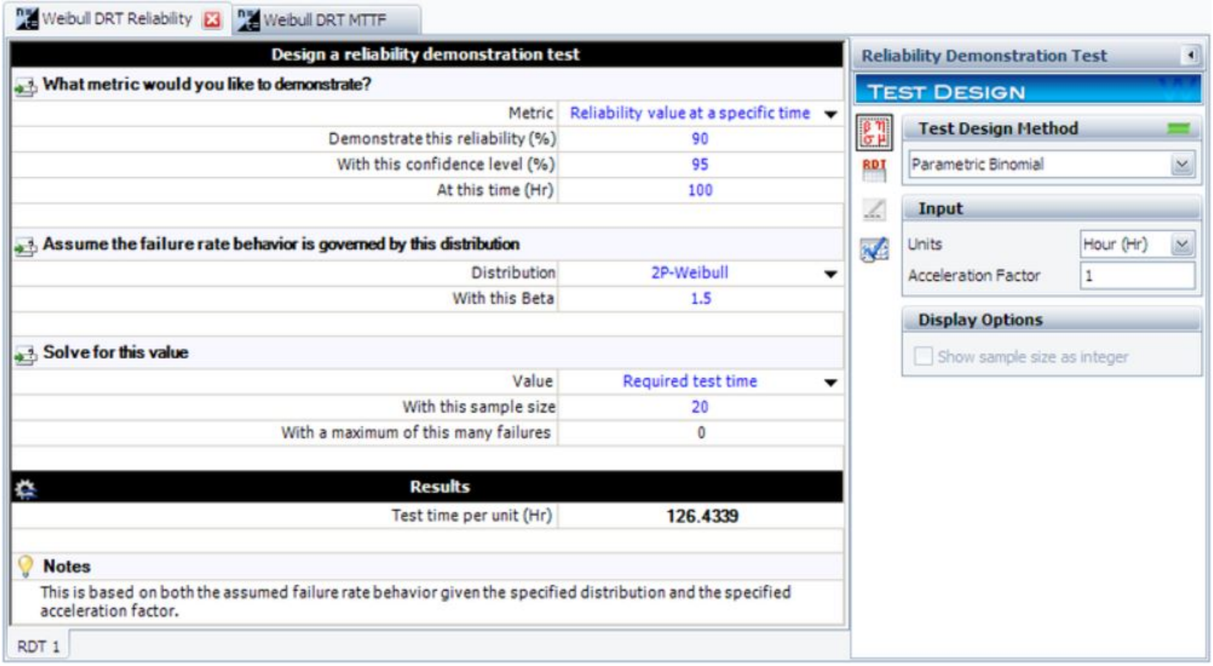
Now we can consider the case where we know the sample size but we want to determine the test time.

✍Example:

In this case, we will assume that we have 20 units to test, $n = 20$, and must determine the test time, t_{test}. We have already determined the value of the scale parameter, η in the previous example. Since we know the values of n, CL, f, η and β, it remains to solve the binomial equation:

$$1 - \text{CL} = \sum_{i=0}^{f} \frac{n!}{i!(n-i)!} \cdot \left(1 - e^{-(t_{\text{test}}/\eta)^{\beta}}\right)^{i} \cdot \left(e^{-(t_{\text{test}}/\eta)^{\beta}}\right)^{(n-i)} \qquad (16.7.932)$$

with the Weibull distribution for t_{test}. This value is $t_{\text{text}} = 126.4339$ hours. This example solved in Weibull++ is shown next.



Design a reliability demonstration test

What metric would you like to demonstrate?

Figure 16.291: **Weibull reliability test time with Weibull++**

16.7.7.3 Test to demonstrate MTBF (or MTTF)

Designing a test to demonstrate a certain value of the MTBF is identical to designing a reliability demonstration test.

✍**Example:**

We want to use the parametric binomial method to design a test that will demonstrate $\text{MTBF} = 75$ hours with a 95% confidence if no failure occur during the test $f = 0$. We will assume a Weibull distribution with a shape parameter $\beta = 1.5$. We want to determine the number of units to test for $t_{\text{text}} = 60$ hours to demonstrate this goal.

The first step in this case involves determining the value of the scale parameter η from the MTBF equation. The equation for the MTBF for the Weibull distribution is for recall:

$$\text{MTBF} = \eta\Gamma\left(1+\frac{1}{\beta}\right) \qquad (16.7.933)$$

This can be rearranged in terms of η:

$$\eta = \frac{\text{MTBF}}{\Gamma\left(1+\dfrac{1}{\beta}\right)} \qquad (16.7.934)$$

Since MTBF and β have been specified, it is a relatively simple matter to calculate $\eta = 83.1$. From this point on, the procedure is the same as the reliability demonstration example. Next, the value of R_{test} is calculated as:

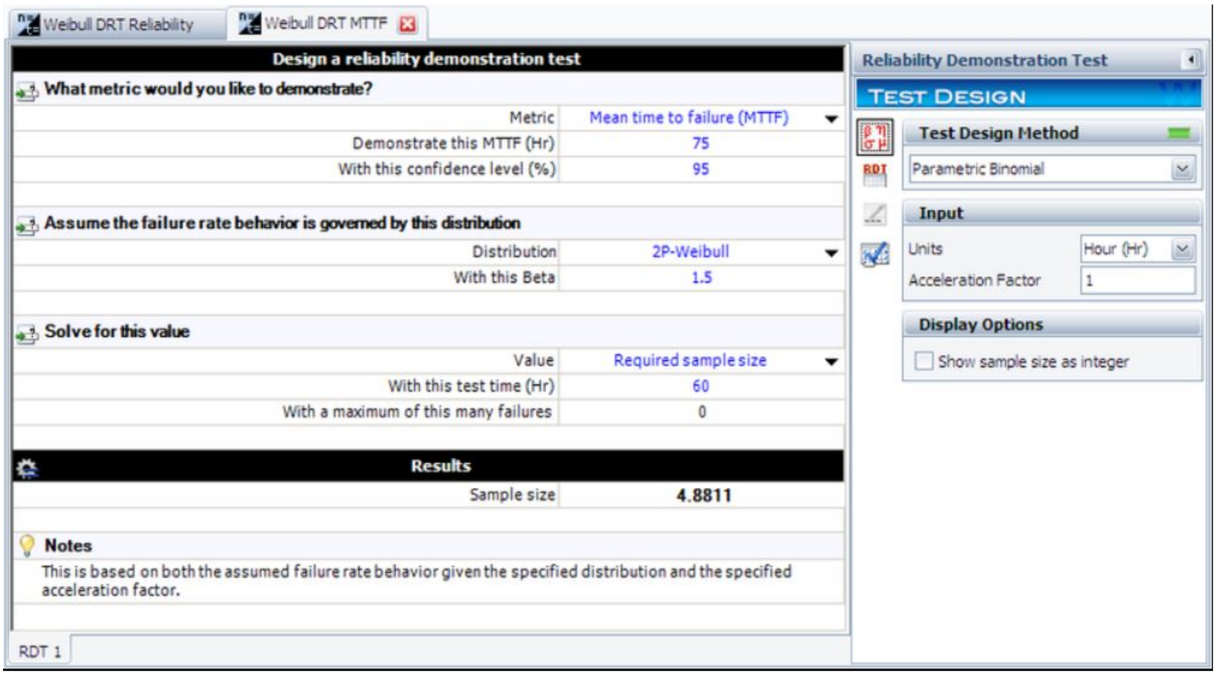
$$R_{\text{test}} = e^{-(t_{\text{test}}/\eta)^{\beta}} = e^{-(60/83.1)^{1.5}} = 0.541 = 54.1\% \qquad (16.7.935)$$

The last step is to substitute the appropriate values into the cumulative binomial equation. The values of CL, t_{test}, β, f and η have already been calculated or specified, so it merely remains to solve the binomial equation:

$$1-\text{CL}=\sum_{i=0}^{f}\frac{n!}{i!(n-i)!}\cdot\left(1-e^{-(t_{\text{test}}/\eta)^{\beta}}\right)^{i}\cdot\left(e^{-(t_{\text{test}}/\eta)^{\beta}}\right)^{(n-i)} \qquad (16.7.936)$$

for n.

The value is calculated as $n=4.8811$, or $n=5$ units, since the fractional value must be rounded up to the next integer value. This example solved in Weibull++ is shown next.



Design a reliability demonstration test

What metric would you like to demonstrate?

Metric	Mean time to failure (MTTF)
Demonstrate this MTTF (Hr)	75
With this confidence level (%)	95

Assume the failure rate behavior is governed by this distribution

Distribution	2P-Weibull
With this Beta	1.5

☐ Show sample size as integer

Figure 16.292: **Weibull reliability sample size for MTBF test with Weibull++**

The procedure for determining the required test time proceeds in the same manner, determining η from the MTBF (or MTTF) equation, and following the previously described methodology to determine t_{test} from the binomial equation with Weibull distribution.

16.7.7.4 Beta-binomial sampling size

The regular nonparametric analysis performed either on the binomial or the chi-squared equation were done with only the direct system test data. However, if prior information regarding system performance is available, it can be incorporated into a Bayesian nonparametric analysis. This subsection will demonstrate how to incorporate prior information about system reliability and also how to incorporate prior information from subsystem tests into system test design.

Thus, since R is bounded in the interval $[0,1]$ a well-known prior is the beta distribution (see section Statistics page 760). We proved in the section Statistics during our study of Bayesian inference that the posterior was then a beta-binomial distribution (see section Statistics page 898) for which we had specified that reliability engineers noted the cumulative probability under the somewhat unfortunate notation:

$$B(N-f+a,f+b) \tag{16.7.937}$$

Therefore, we have in our case a posteriori:

$$1-\text{CL}=B(N-f+a,f+b) \tag{16.7.938}$$

We know f which is imposed to us by the demonstration plan, we are always trying to determine N. We know that for the beta law:

$$P_{a,b}(x)=\frac{x^{a-1}(1-x)^{b-1}}{B(a,b)}1_{]0,1[} \tag{16.7.939}$$

that we have:

$$\mu=\frac{a}{a+b} \qquad \sigma^2=\frac{ab}{(a+b)^2(a+b+1)} \tag{16.7.940}$$

With a little elementary algebra we get:

$$a=\mu\left[\frac{\mu-\mu^2}{\sigma}-1\right] b \quad =(1-\mu)\left[\frac{\mu-\mu^2}{\sigma}-1\right] \tag{16.7.941}$$

The question is then what to do now ...? Then here the statistician engineer uses a trick ... It takes the generalized beta law with 4 parameters including thus the famous optimistic, pessimistic interval $[O,P]$ that we studied in the section of Quantitative Management (see page 8074) and uses the corresponding relation of mean and variance that we have proved:

$$\begin{aligned}\mu=\text{E}(R)&=\frac{O+4M_0+P}{6}\\ \sigma^2=\text{V}(R)&=\left(\frac{P-0}{6}\right)^2\end{aligned} \tag{16.7.942}$$

Where normally we should use for the modal value as we have proved in the section of Quantitative Management:

$$M_0=\frac{2(O+P)+\sqrt{2}(b-a)}{4} \tag{16.7.943}$$

but the overwhelming majority of engineering project management and reliability software make the fundamental error of asking the modal value to the user (we will see a concrete example a little later with the most famous reliability software used in the USA).

Once this is done. The idea is to return to a beta law with two parameters by injecting the values of expectation and variance obtained by the beta law with 4 parameters in:

$$\begin{aligned}a&=\mu\left[\frac{\mu-\mu^2}{\sigma}-1\right]\\ b&=(1-\mu)\left[\frac{\mu-\mu^2}{\sigma}-1\right]\end{aligned}\tag{16.7.944}$$

which obviously imposes indirectly that beta laws with 4 and 2 parameters have then same variance and even expectation!

✍**Example:**

Consider that an engineer wants to set up a demonstration plan in order to demonstrate that the reliability of its product is 90% with an 80% confidence level assuming that a single failure is allowed and that the engineer believes that the optimistic reliability is of $O=87\%$, the most likely (modal) value of $M_0=90\%$ and the greatest reliability is equal to $P=99\%$.

We have then:

$$\begin{aligned}\mu&=\text{E}(R)=\frac{O+4M_0+P}{6}=0.91\\ \sigma^2&=\text{V}(R)=\left(\frac{P-0}{6}\right)^2=0.0004\end{aligned}\tag{16.7.945}$$

and thus the parameters of the beta law with two parameters are then:

$$\begin{aligned}a&=\mu\left[\frac{\mu-\mu^2}{\sigma}-1\right]=185.4125\\ b&=(1-\mu)\left[\frac{\mu-\mu^2}{\sigma}\right]=18.337\end{aligned}\tag{16.7.946}$$

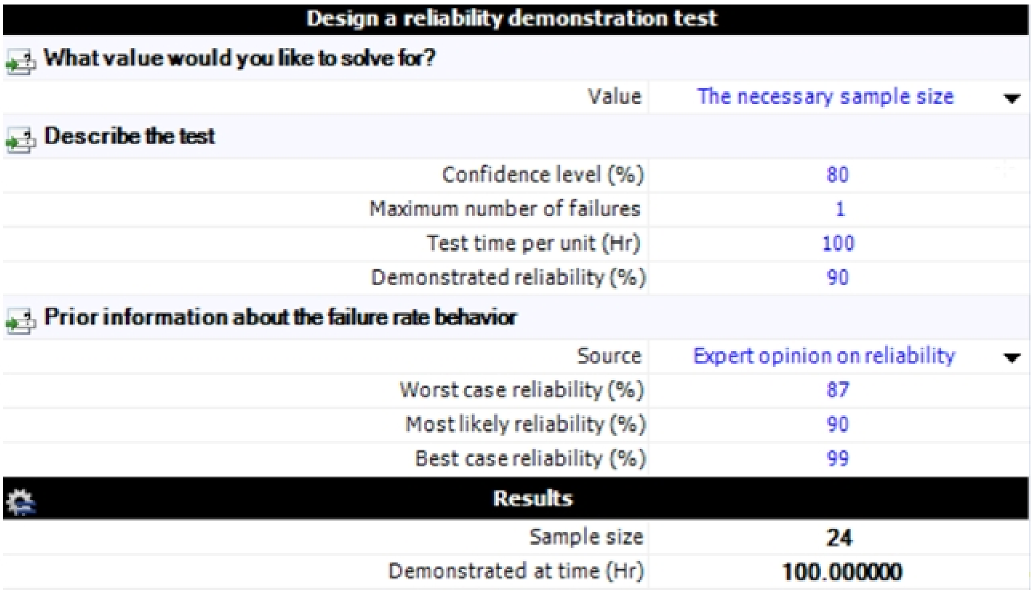
We must then find N such that:

$$1-\text{CL}=20\%=B(N-f+a,f+b)=B(N+184.4125,19.337)\tag{16.7.947}$$

It is easy to get N with a spreadsheet software like Microsoft® Excel® using the BETA.DIST with Microsoft® Excel® 2007 and higher:

```
= BETA.DIST(90%;N+184.4125-1;19.337;1)
```

And with the Goal Seek tool, we get the result $N=24$ by rounding to the nearest integer. This corresponds well to the Weibull++ software output (see next page):



Design a reliability demonstration test

What value would you like to solve for?

Value	The necessary sample size

Describe the test

Confidence level (%)	80
Maximum number of failures	1
Test time per unit (Hr)	100
Demonstrated reliability (%)	90

Prior information about the failure rate behavior

Source	Expert opinion on reliability
Worst case reliability (%)	87
Most likely reliability (%)	90
Best case reliability (%)	99

Results

Sample size	**24**
Demonstrated at time (Hr)	**100.000000**

Figure 16.293: **Beta-Binomial sample size demonstration plan in Weibull++ 7 software**

It is interesting to know that if the modal value M_0 had been calculated rather than requested, we would have therefore $N=-30$ since in the latter case $M_0=97.246\%$... So we see that every model has obviously its limits...

If we use the same parameters with $O=87\%$, $M_0=90\%$, $P=99\%$ with our case but now with the Binomial law that we used in the first example above, then the result rounded to the nearest integer givs $N=13$.

Epilogue

You have travelled a long distance with us through this textbook. We have now reached the epilogue, where by tradition, the main redactor is allowed to give voice its own personal opinions.

Indeed, I want to leave you with some of my thoughts on theory versus practice, business and engineering education, applied mathematics research, and what I hope you will take with you after having read this textbook.

By nature, academic engineering is very closely related to its practice. Theory and practice are ruled by the same ideas. As an academic myself teaching since 12001 (holocene calendar) in Fortune 500 and SME companies, I am proud to claim that the majority of engineering ideas were either invented or developed in academia first before they crossed over into practice.

But engineering research is not just for aspiring academics! As I know it very well management and economics consultants are basically researchers even if most of them have a very low analytic level. Firms like McKinsey, Ernst & Young, KPMG and Accenture may have different audiences, production speeds, team systems, and publication and evaluation processes, but they research the same issues that academics do and with the same methods at the exception that the level is significantly lower.

There is also much cross-fertilization! Many professors work regularly with major consulting or asset-investment firms and some have even quit academia altogether to quadruple their pay (or increase their global happiness...).

Because engineering is by nature such an applied discipline, after reading this textbook, you should probably not need anything else to understand engineering research today. In an ideal World, you should be able to read the current state-of-the-art research right now.

So, do we really understand engineering? Certainly not fully! We haven seen through this textbook that engineering is as much an art as it is a science. Given our deficiencies, given that all our methods have their errors, what should we do? My best advice to you is to use common sense, to employ a number of different techniques to come up with a range of possible answers, avoid cognitive biases, and to then make a judgement at the end of the day as to what estimate appears most reasonable in light of different models and your peer-reviewers.

Our book has covered the principles of engineering in some depth and breadth. You should be very well prepared now for the next steps in your lifetime engineering education.

I have enjoyed compiling this textbook in the same way that I enjoy writing my training books, and pretty much for the same reason: It has been like solving an intriguing puzzle that no one else has figured out in quite the same way a particular way to see and explain finance. Of course, compiling it has taken me quite a long times (20 years, without translation: 15 years!).

But it will all have been worth it if you have learned from it. If you have studied the book, you should now know about 99% of what I know about engineering. Interestingly, there were a number of topics that I thought I had understood, but had not - and it was only my having to explain them to you that clarified them for me, too. And this brings me to a key point that I want to leave you with - never be afraid to ask questions, even about first principles! To do so is not a sign of stupidity on the contrary, it is often a sign of deepening awareness and understanding.

I have no illusions: You will very likely not remember all the fine details in this textbook as time passes - I know I won't. But more than the details, I hope that I will have left you with an appreciation for the big ideas, an arsenal of tools, a method for approaching novel problems, and a new perspective. You can now think like an Engineer or even better: as a Scientist!

KNOWLEDGE

Biographies

To be informed of Nobel laureates (physics, chemistry, economics), Fields Medal... click this link Nobel Prizes or on this one Fields Medal.

This section contains a list of some humans who have a strange reputation. Under the rules of history that is taught in elementary school, they do not exist, they haven't ordered any army, they sent nobody to death, they did not have any empire and they had only a minor part in major historical decisions. Some have acquired some celebrity, but none was ever a national hero. Yet their work has more influenced on the course of history than many acts by statesmen crowned with a far greater glory. They produced more turmoil than the comings and goings of armies in battle over borders, they have done more for the happiness or unhappiness that the edicts of kings and assemblies, because their work, is to have shaped the mind of man!

The one who spreads his ideas has a power much greater than that of the sword or sceptre: this is why they have shaped and directed the world. For the most part they have not lifted any finger to act physically, they worked mainly as intellectuals, in silence and oblivion, without worrying of the surrounding world. But in their wake, empires have crumbled, political regimes have either strengthened or eroded, the classes were pitted against each other, and also did nations. Not under the influence of a dark conspiracy, but by the extraordinary power of their ideas. Who are these humans?: Scientists, economists, chemists, biologists, mathematicians, physicists, computer scientists, engineers, ...

The biographies below of the most famous scientists around the world and cited in the various chapters of this textbook are sorted alphabetically and almost all texts are simplify a copy/paste of the French Wikipedia (and translated afterwards in english).

We also pay tribute to the millions of scientists[1], engineers, philosophers, craftsmen, artists, known and anonymous amateurs whose collaboration enabled through millennia the evolution of science and of the human condition!

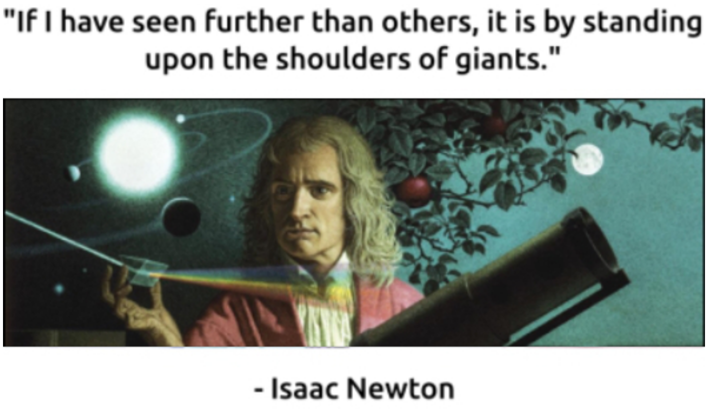
The sizes of the biographies are not proportional to the number of articles published or to the discoveries made, but to the amount of information found on the Internet or in the literature.

---

[1] It seems that at the start of this third millennium there are not far from seven million high-level scientists around the World according to UNESCO statistics.

The list is also not exhaustive, but its purpose is to honour and remember the great humans who made of pure sciences what they are today and who have spent part or whole of their life to science: most constrained art.

> Caution! In physics (as well in mathematics) a theory, an equation or even a constant rarely wears the name of its true inventor. This is widely known among scientists and is often a source of joke from the community.

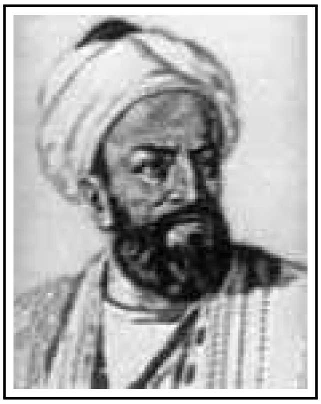


"If I have seen further than others, it is by standing upon the shoulders of giants."

- Isaac Newton

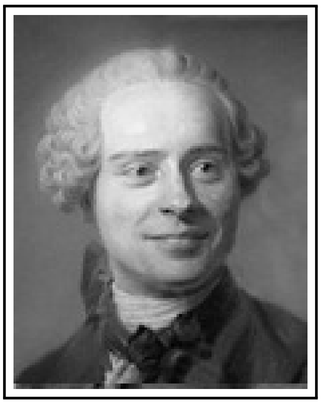
The reader will notice that as for the biggest part of this textbook, the years below are given on the basis of the Holocene scientific calendar and not on the basis of one of the many religious calendars (based on fairy tales and legends) existing in the world and this for obvious reasons...

A B C D E F G H I J K L M N O P Q R S T U V W X Y Z



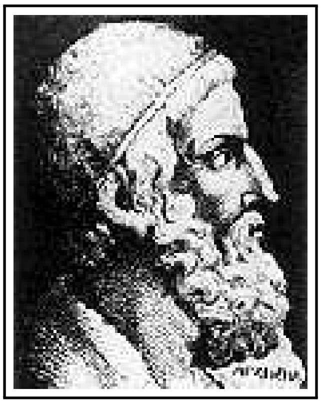
Al-Biruni, Muhammad Ibn Ahmad Abul-Rayhan (10973-11048) is a mathematician, astronomer, physicist, encyclopedist, philosopher, astrologer, traveller, historian, pharmacologist and a tutor, native of Persia, who contributed greatly to the fields of mathematics, philosophy, medicine and science. He is known for his theory on the Earth's rotation around its axis and around the Sun, and this long before Copernicus. He focused particularly on the calculation of the Sun running (apogee) and also corrected some data of Ptolemy. Excellent mathematician, Al-Biruni developed new equations unknown to his predecessors. He calculated also the local meridian and the coordinates of some localities. But the picture would not be complete if we forgot to mention that six centuries before Galileo, Al Biruni already put forward an Earth that revolved around its axis. With the help of an astrolabe, the sea and a nearby mountain, he calculated the circumference of the Earth by solving a complex equation for its time. The main contribution of Al-Biruni to mathematics lies in its work in trigonometry (calculations of some trigonometric functions values that were not well defined at this time).

Al-Kindi, Abu Yūsuf Ya'qūb ibn (10801-10873) born in Kufa and educated in Baghdad is a philosopher, polymath, mathematician, physician and musician. Al-Kindi was the first of the peripatetic philosophers, and is unanimously hailed as the "father of Arab philosophy" for his synthesis, adaptation and promotion of Greek and Hellenistic philosophy in the Muslim world. In the field of mathematics, Al-Kindi played an important role in introducing Indian numerals to the Islamic and Christian world. Al-Kindi was also one of the fathers of cryptography. His book entitled *Manuscript on Deciphering Cryptographic Messages* (obviously the original title wasn't in english...) gave rise to the birth of cryptanalysis, was the earliest known use of statistical inference, and introduced several new methods of breaking ciphers. Using his mathematical and medical expertise, he was able to develop a scale that would allow doctors to quantify the potency of their medication. According to Ibn Al-Nadim, Al-Kindi wrote at least two hundred and sixty books, contributing heavily to geometry (thirty-two books), medicine and philosophy (twenty-two books each), logic (nine books), and physics (twelve books).



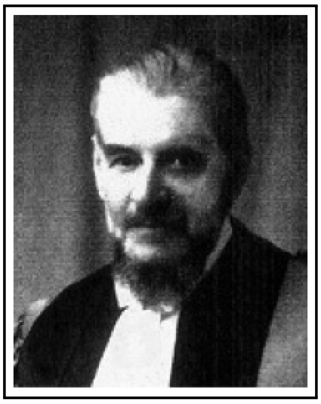
Alembert, Jean le Rond (11717-11783), child of a commissioner of artillery, abandoned on the steps of the chapel of Paris Saint-Jean-Le-Rond, the future great philosopher, mathematician and physicist is adopted by a glazier who secretly receive a pension to support the education of the young boy who brilliantly study law, medicine and mathematics. Following the publication of several memoirs (on integral calculus and refraction of solids), d'Alembert entered the Academy of Sciences (11741). He is at the origin of the famous momentum principle, named "D'Alembert's principle" in his *Traité de dynamique* (11743). In astronomy, he is the author of a treaty on the precession of the equinoxes (11749) explained by using the Newton theory of universal gravitation and with a partial solution to the three bodies problem. D'Alembert also establishes a mathematical theory of vibrating strings by studying the nature of the sound (harmonics).

Ampère, André Marie (11775-11836) at eighteen years old, he already knows most of the mathematical works of his time. First-class mathematician, he shows how we must use this science, that he was considering as a branch of philosophy, to the study of physical facts to give a definitive relation. Within a few weeks, Ampere gives the foundation to a science to which he gives the name of "Electromagnetism". He tries to understand the magnetism of magnets and draws a hypothesis of "particulate flows" (today: electronic orbits spin orientation). It also equal the number of molecules in equal volumes of gases of different nature, but measured under identical conditions of temperature and pressure (experimental observation of Gay-Lussac).



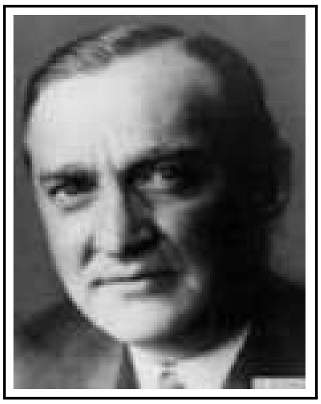
Archimedes of Syracuse (9713-9788), is a famous Greek mathematician and engineer as both a theorist and as a mechanic machine manufacturer. Archimedes had an exceptional mathematical production, part of which was received in treaties such as *On the Sphere and Cylinder*, *Measurement of the circle; Quadrature of the parabola, spiral and the conoid and spheroids*; *The Method of Bodies floating*... This is from his mechanical work that the main legends starts, like the lever or the bath, will be. The famous maxim: « Give me a place to stand and I will move the Earth» is an echo of the popular Archimedean contribution to the static in the treaty of Equilibria. Archimedes proves the law of the lever, introduces the basic concept of center of gravity, and determines the centroids for the main plane geometric figures. It is the same for the story of Archimedes springing naked from his bath, crying «Eureka», because he came, following the legend, to solve the problem posed to him by King Hiero. In fact, the story is a spectacular staging of the discovery of the fundamental principle of hydrostatics (commonly named "Archimedes principle"). In geometry, the work of Archimedes develops that of Eudoxus of Cnidus as we know it by the book XII of *Euclid's Elements* (obviously the original title wasn't in english...): this is to compare measurements of plane figures and solids, in particular from curvilinear figures. Thus, Archimedes proved that the volume of the circumscribing cylinder of a sphere is equal to one and half times it's volume and that the side surface of the cylinder is equal to that of the sphere or four times the surface of a great circle. So if we can calculate the area of the circle, we know that of the sphere, cylinder, its volume and that of the sphere, etc. His most famous result and easiest is for the circle. Archimedes brings it's quadrature to another problem: the correction of its circumference, that is to say "find a equal straight line to it is equal", it solves the problem using a geometric curve that is now named "Archimedean spiral". In addition, it calculates the approximate values of the circumference/diameter ratio (what we name the number "Pi" noted π).

Avogadro, Amedeo (11776-11856), son of a magistrate of Turin, Amedeo begins his life by following his father path. He pass a law degree in 11795 and practice in his hometown. But his love for physics and mathematics, which he studied alone, drives him to start on the late scientific studies. In 11809 he presents a paper to the Royal Academy of Turin; its success allows him to get a professorship at the Royal College of Vercelli. In 11820, the University of Turin created for him a chair of Physics that he will keep until the end of his life. By studying the laws governing the compression and expansion of gases Avogadro states, in 11811 the hypothesis famously known as "Avogadro's law". Based on the atomic theory of Dalton's and Gay-Lussac law on the volume ratios, Avogadro's theory indicates that two equal volumes of different gases, under the same conditions of temperature and pressure, contain the same number of molecules. Under it's seeming simplicity, this law has important implications, because of it, it becomes possible to determine the molar mass of a gas from one another. But the chemists at this time, more interested in experiences, are not attentive to the theoretical studies of Avogadro who will also be recognized only fifteen years later. The name Avogadro also remains linked to that of "Avogadro's number" indicating the number of molecules in one mole.

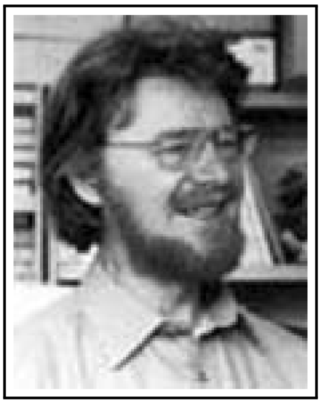


Bachelier, Louis (11870-11946) was born in Le Havre in a family of merchants. He appears at his majority on the electoral lists of Le Havre in 11892 as a sales representative at the same business address as his father. After completing his military service at age 22, he resumed his studies at the Faculty of Sciences in Paris. He obtained a Bachelor of Science in 11895 (passing grade) and a PhD in 11900 with his famous and unknown subject in mathematics... Although his theory is now considered as a pioneering work in probability and financial theory. From 11913 to 11914 Bachelor teaches probability theory applied to mechanics, ballistics, and biometrics. He was also responsible for additional conferences on general mathematics from 11913 to 11914. It is only after the 11914-11918 war that he obtained a first post of lecturer at the Faculty of Besançon. After several replacements in Dijon and Rennes, he returned to Besançon in 11927 as chair Professor of Calculus, a position he held until his retirement in 11937. Louis Bachelier, among his numerous works, was the first to have introduced the continuity in probabilities problems taking time as a variable. In particular, he developed a mathematical theory of Brownian motion five years before Albert Einstein. He is also, well before Norbert Wiener, the first to have defined the function of Brownian motion and gave many of its properties.

Balmer, Johann Jakob (11825-11898) was a Swiss mathematician and mathematical physicist born in Lausanne (Switzerland) and who died in Basel. During his schooling he excelled in mathematics, and so decided to focus on that field when he attended university. He studied at the University of Karlsruhe and the University of Berlin, then completed his PhD from the University of Basel in 11849 with a dissertation on the cycloid. Johann then spent his entire life in Basel, where he taught at a school for girls. He also lectured at the University of Basel. Despite being a mathematician, he is not remembered for any work in that field; rather, his major contribution (made at the age of sixty, in 11885) was an empirical formula for the visible spectral lines of the hydrogen atom, the study of which he took up at the suggestion of Eduard Hagenbach also of Basel. A full explanation of his formula worked, however, had to wait until the presentation of the Bohr model of the atom by Niels Bohr in 11913.

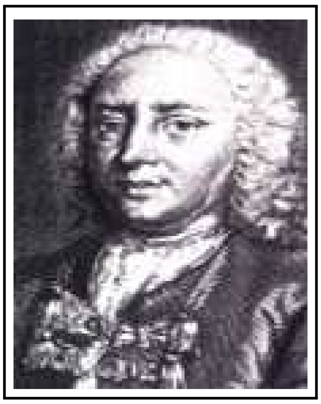


Banach, Stefan (11892-11945) was a Polish mathematician who defined the foundations of functional analysis. Born in Krakow in 11892, Austria-Hungary (now Polish city). Banach went to high school in Krakow, where he revealed to be particularly brilliant in mathematics and natural sciences, but his disinterest in other matters prevented him from obtaining the best evaluation. Banach's life (at least mathematically) will switch in the spring of 11916, when he meets Steinhaus in Krakow. With Otto Nikodym, they decided to find a mathematical society. Banach's mathematical research begins at this moment. His first article was co-authored with Steinhaus. Steinhaus told him about a property he could not be able to prove, and after some days of reflection, Banach exhibited a cons-example. It is difficult to say what would have happened to Banach's mathematical activity without the meeting with Steinhaus, but the fact remains that he began only after it's intense and fruitful researches. Banach returns in Lvov in 11920 as an assistant. He submitted his thesis in 11922, and it is in this thesis that appears for the first time the notion of Banach space and where the fundamentals theorems about these objects are prove and also and also where there is a discussion on weak topology... In short, this thesis marks the birth of functional analysis. In 11929, he founded with Steinhaus the magazine *Studia Math*, dedicated to the development of functional analysis, and in 11939 he was elected president of the Mathematical Society of Poland. In 11945, shortly before the end of World War II, he died of a long cancer. Many theorems are associated with the name Banach, that he has demonstrated himself, or that they refer to it's ideas. These include: the theorem of Hahn-Banach about the extension of continuous linear forms, the theorem of Banach-Steinhaus, Banach-Alaoglu, the Banach fixed point theorem of course the Banach-Tarski paradox.

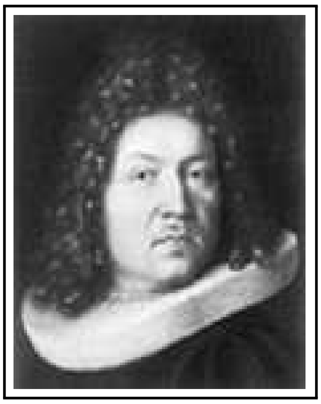


Bell, John (11928-11990) was from earliest childhood attracted to books about science. Because of family financial problems, he could not immediately follow academic studies. He then worked for a year as a technician in the physics department of Queen's University in Belfast before becoming a student in 11945 in the same department. He went out first rank in his class in math-physics. Bell founded in the years 11960 a new inspiration in the foundations of quantum theory, an area supposedly exhausted by the results of the Bohr-Einstein debate thirty years earlier, and ignored by almost everyone who used the quantum theory-between time. Indeed, Bell was intrigued by the Heisenberg quantum uncertainty and wanted to delve deeper by showing that the discussion of concepts such as "realism", "determinism" and "locality" could be affiliated in a rigorous mathematical relation: "the Bell inequalities" experimentally verifiable. Bell pushed very far the doubts he had on the principles of uncertainty to the point that even irritated his teacher (Sloane) who told him that now he was going too far! Bell waited for his thesis to develop his ideas. Unfortunately, because of financial problems again, he had to delay his research and join the Harwell atomic research center. During his career, he married a woman (Mary Bell) who helped him in the development of its work on the fundamentals of quantum theory. It is in 11951, with Rudolf Peierls, that Bell developed his famous CPT theory (Charge, Parity, Time). Unfortunately for Bell, Gerhard Lüders and Wolfgang Pauli came to the same result in the same period and it is to them that were awarded this discovery. The theoretical developments of Bell are at the origin of cryptography and quantum information theory. Another major work of Bell in 11969 was the participation in the development of "the A.B.J. anomaly" (Adler-Bell-Jackiw) in quantum field theory. This three physicists showed that the standard algebraic model merely an error. Indeed, quantification of the fields model broke a symmetry. Bell was nominated for the Nobel Prize, that he certainly would have obtained if he had not died in 11990.

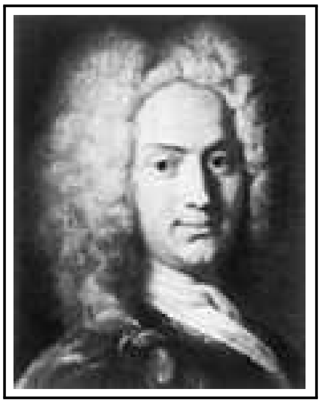
Berners-Lee, Timothy John (11955-) is an English physicist best known as the inventor of the World Wide Web. He is the director of the World Wide Web Consortium (W3C), which oversees the continued development of the Web. He is also the founder of the World Wide Web Foundation, and is a senior researcher and holder of the founders chair at the MIT Computer Science and Artificial Intelligence Laboratory. He is a director of the Web Science Research Initiative (WSRI), and a member of the advisory board of the MIT Center for Collective Intelligence. He worked as an independent contractor at CERN from June to December 11980. While in Geneva, he proposed a project based on the concept of hypertext, to facilitate sharing and updating information among researchers. The address info.cern.ch was the address of the world's first-ever web site and web server, running on a NeXT computer at CERN. The first web page address was http://info.cern.ch/hypertext/WWW/TheProject.htm.



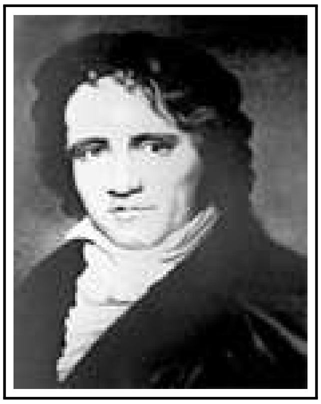
Bernoulli, Daniel (11700-11782) was a Swiss scientist who discovered the basic principles of behaviour of a fluid (it is also the son of Johann Bernoulli and the nephew of Jacques Bernoulli). He cultivated both mathematics and natural sciences, taught mathematics, anatomy, botany and physics. Friend of Leonhard Euler, he worked with him in several areas of mathematics and physics (he shared with him ten times the annual prize of the Academy of Sciences of Paris), he made this prize a kind of income. The various problems he tried to solve (elasticity theory, mechanism of tides) led him to focus and develop mathematical tools such as differential equations or series. He also collaborated with Jean le Rond d'Alembert in the study of vibrating strings. He studied the flow of fluids (11738) and formulated the principle (the famous Bernoulli theorem) that the pressure exerted by a fluid is inversely proportional to its velocity. He used atomistic concepts to outline the first kinetic theory of gases, expressing their behaviour in terms of probabilities under the particular conditions of pressure and temperature. He can be regarded as a founder of hydrodynamics.



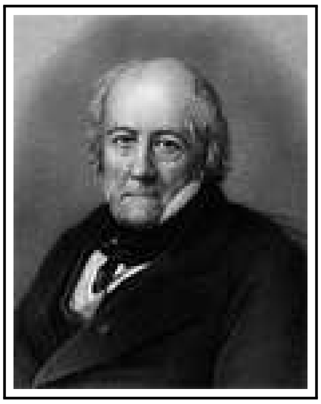
Bernoulli, Jacques (11654-11705), was a Swiss mathematician and physicist, brother of Jean Bernoulli and Daniel Bernoulli and the uncle of Nicolas Bernoulli. Born in Basel in 11654, he met Robert Boyle and Robert Hooke on a trip to England in 11676. After that, he devoted himself to physics and mathematics. He teaches at the University of Basel from 11682, becoming professor of mathematics in 11687. He earned by his work and discoveries to be made a member of the Academy of Sciences in Paris (11699) and that in Berlin (11701). His correspondence with Gottfried Wilhelm Leibniz leads him to study infinitesimal calculus in collaboration with his brother Jean. He was among the first to understand and apply the integral and differential calculus, proposed by Leibniz, discovered the properties of numbers named "Bernoulli numbers" and gave the solution of problems considered at his time as insoluble. He sets out the principles of probability theory and introduced the Bernoulli numbers in a book published after his death in 11713.



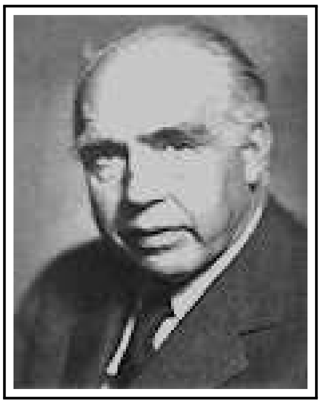
Bernoulli, Jean (11667-11748), was a Swiss mathematician and physicist. Jacques Bernoulli's brother and father of Daniel and Nicolas Bernoulli. He taught mathematics at Groningen (11695), then in Basel, after the death of Jacques Bernoulli (11705), and became a member of the Academies of Sciences in Paris, London, Berlin and St. Petersburg. Trained by his brother Jacques Bernoulli, he had long worked with him to develop the implications of the new infinitesimal calculus invented by Gottfried Leibniz, but he then appears between them on the occasion of solving some problems, a rivalry which degenerated into enmity. He also contributed in many areas of mathematics including the problem of a particle moving in a gravitational field. He found the equation of the chain in 11690 and developed the exponential calculation in 1691. He also had the honour to train Leonhard Euler. He came to Paris in 11690 and became intimate with the most distinguished scholars, especially with Hospital. Jean Bernoulli became a member of the Royal Society in 11712.



Bessel, Friedrich (11784-11846) Born in Minden, Westphalia, Bessel began working very young as a clerk. Attracted by shipping, he became interested in nautical observations, constructing his own sextant and studying astronomy in his free time. He calculated the trajectory of Halley's comet, a result which was immediately released and allowed him to obtain, in 11806, a job as assistant at the Lilienthal Observatory. In 11810 he became director of the new observatory in Königsberg, while pursuing mathematical studies. He had to teach mathematics to his students in astronomy until 11825 (when Jacobi came to teach the subject in Königsberg). His whole life was devoted to astronomy (he wrote over 350 articles) and, shortly before his death, he began the study the motion of Uranus, the problem that led to the discovery of Neptune. In mathematics, Bessel is known for introducing the functions that have his name, used for the first time in 11817 for the study of a Kepler problem, and employing more fully seven years later to study planetary perturbations.

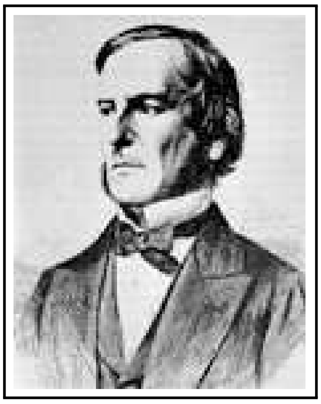


Biot, Jean-Baptiste (11774-11862) born and died in Paris was a physicist, astronomer and mathematician. Jean-Baptiste followed secondary education (humanities) in Paris at the Collège Louis-le-Grand until 11791. He began studying engineering at the École des Ponts et Chaussées in January 11794, then joined the École Central des Travaux Publiques (later Polytechnic) when it opened in December 11794 at the Palais Bourbon. One year later (11795) he joined the École des Ponts et Chaussées to complete his training as an engineer. It is to teaching that Biot oriented his career after studying engineering. He became professor of mathematics at the École Central de l'Oise in Beauvais in 11797. With the support of Laplace he was appointed in 11800, aged 26, as professor of mathematical physics at the Collège de France. He is between 11816 and 1826 responsible at 50% of the trainings of physical acoustics, magnetism and optics, Gay-Lussac, having the chair of Physics, teaches heat, gas, humidity, the electricity and the galvanism. He formulated with Félix Savart, the Biot-Savart law, which gives the value of the magnetic field produced at a point in space by an electric current as a function of distance from this point to the conductor.



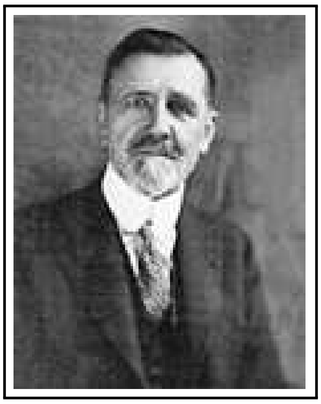
Bohr, Niels Henrik David (11885-11962) was a Danish physicist, Nobel Prize of Physics in 11922 for his contributions to nuclear physics and the understanding of atomic structure. The Bohr theory of atomic structure, for which he received the Nobel Prize, was published between 11913 and 11915. His work was inspired by the nuclear model of the Rutherford atom, in which the atom is considered as a compact nucleus surrounded by a cloud of electrons. The model suppose that the atom emits electromagnetic radiation when an electron moves from one quantum level to another. This model contributed enormously to future developments of theoretical atomic physics.

Boltzmann, Ludwig (11844-11906) was an Austrian physicist who helped to establish the foundations of statistical mechanics. Educated in Vienna and Oxford, he taught physics at several universities in Germany and Austria for over forty years. Developing the kinetic theory of gases, especially from the work of Maxwell, it establishes that the second law of thermodynamics could be obtained on the basis of statistical analysis. Calculating the number of particles with a given energy, he established the so-named "Maxwell-Boltzmann statistical". He expressed the entropy S of a system according to the probability W of his state (through his famous equation of transport from which he showed that entropy could only increase over time ... result which was previously recognized experimentally but not theoretically proved). It could also establish theoretically the "Stefan's law" concerning the radiation of a black-body. But he had to explain how the mechanics principles, where the phenomena are reversible, could lead to thermodynamic laws describing phenomena characterized by irreversibility. He advanced the idea that irreversible changes, although they are only possibilities among others, are so likely that they are almost always occurring.



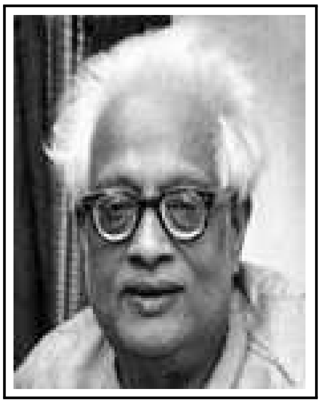
Boole, George (11815-11864) was an English mathematician and logician and the creator of symbolic logic. Born in Lincoln, and son of a shopkeeper, he received his first lessons in mathematics from his father, who also taught him to manufacture optical instruments. Outside advice from his father and several years in local schools, Boole is a self-taught. When his father's business declined, he was obliged to work to help his family and, when sixteen, he taught in village schools, at twenty, he opened his own school in Lincoln. During his hobbies he studied mathematics at the Institute of Mechanics, created around this time, that's where he became acquainted with *Newton's Principia*, Laplace's celestial mechanics and analytical mechanics of Lagrange and he began to solve problems of higher algebra. Boole submitted to the new Cambridge Mathematical Journal a series of original articles, the first being *Searches on the theory of analytical transformations*, these articles focused on differential equations and the invariant linear transformation. In 11844, he studied the links between algebra and infinitesimal calculus in an important paper published in the *Transactions* of the

Royal Society, which awarded him a medal for his contribution to the analysis (that is, the use of algebra in the study of infinitely small and large entities). Developing new ideas about the method in logic and confident in the symbolism he had created from his mathematical research, he published in 11847, a booklet, *Mathematical Analysis of Logic*, in which he argues that the logic must be attached mathematics, not philosophy. Even he had no university degree, Boole was, on the basis of its publications, in 11849 appointed professor at Queen's College in Cork, Ireland. With Boole, in 11847 and in 11854 began the algebra of logic, that is to say, what we name today the "Boolean Algebra". In his book of 11854, Boole states its completely new symbolic method of logical inference, which allows with proposals containing a number of terms, to obtain, by symbolic processing of the premisses, conclusions which were logically contained in the premises. He also search a general method in probability, which would, from the known probabilities of a given event, determine the probability of any other event logically connected to specific events.



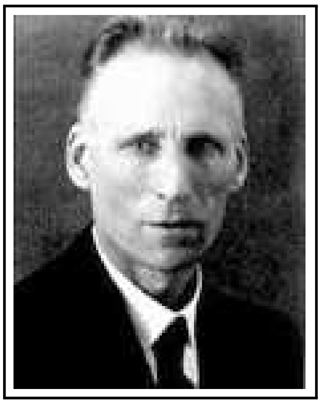
Borel, Emile (11871-11956) was a French mathematician received major at X and ULM, he chooses the last one and dedicated his time to mathematics. He founded the Institute Henri Poincare and was elected mayor of the Aveyron and Saint-Africa. He studies the measures of sets and in particular, defines the sets of measure zero and all Borel sets on which we can define a measure. He then turns to probability and mathematical physics. Borel is also considered a constructivist mathematician. He is at the origin of strategic game theory and cybernetics that will develop later von Neumann and Morgenstern. His pupil Henri Lebesgue use his results in topology and measure theory for his theory of integration.

Born, Max (11882-11970) born in Breslau and died in Göttingen was a German and British physicist. Initially he followed his studies at the College of König-Wilhelm and continued at the University of Breslau followed by Heidelberg and Zürich Universities. While studying for his PhD he came in contact with mathematicians such as Klein, Hilbert, Minkowski, Runge, Schwarzschild. In 11921, he was appointed professor of theoretical physics at Göttingen. He emigrated to Scotland in 11933 and became a British citizen in 11939. Outstanding theoretical physicist, he is known for his significant contribution to quantum physics: Development (11925) of quantum matrix mechanics introduced by Werner Heisenberg and, most importantly, he will be the first to give to the square of the modulus of the wave function the meaning of a density of probability of presence. He was also a pioneer in the quantum theory of solids (conditions of Born-von Karmann) and non-linear electrodynamics of Born-Infeld. He has won half of the Nobel Prize for Physics in 11954 (the other half was given to Walther Bothe) for his fundamental research in quantum mechanics, especially for his statistical interpretation of the wave function. The Royal Society awarded him the Hughes Medal in 11950.

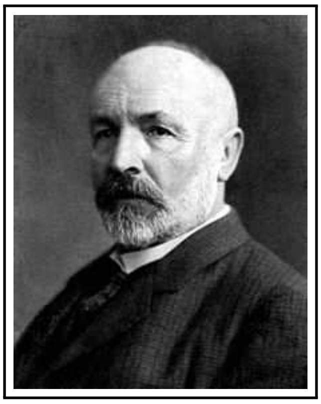


Bose, Satyendranath (11894-11974) was an Indian mathematician and physicist, known for his contributions to quantum theory. Born in Calcutta, Bose was educated at Presidency College in Calcutta. In 11924, he offers a statistical description of quantum systems, echoed by Albert Einstein, which places no restrictions on the energy distribution of particles in the system. This description is known as the "Bose-Einstein statistics", as opposed to the "Fermi-Dirac statistics". Applied to the theory of black-body radiation, this new statistic leads to the "Planck distribution" and treats this radiation as a photon gas. In the field of elementary particle physics, the Bose-Einstein statistics requires the wave function of particles (in the Schrödinger equation) to be perfectly symmetrical for all the variables of space and spin. Particles obeying these statistics (photons, mesons π, etc.) are named "bosons". Professor of physics at the Universities of Calcutta and Dhaka, Satyendranath Bose was appointed in 11958 National Teacher of India.

de Broglie, Louis Victor (11892-11987) was a French physicist and Nobel laureate who brought an essential contribution to the quantum theory with his studies of electromagnetic radiation. Born in Dieppe, Louis de Broglie was educated in Paris. He tried to understand the dual nature of matter and energy and suggested the association of a wave with any particle. He proposed also directly to explain how it was possible to obtain the quantization rules of Bohr and Sommerfeld atom's model requiring an integer number of waves in a stationary orbit. His discovery of the wave nature of electrons (11924) won him the Nobel Prize for Physics in 11929, however, he did not proposed a wave equation describing quantum phenomena (what Schrödinger will). He was elected to the Academy of Sciences in 11933 and at the Académie Française in 11943. He was appointed professor of theoretical physics at the Université de Paris (11928), Permanent Secretary of the Academy of Sciences (11942), and advisor to the Atomic Energy Commission (11945).

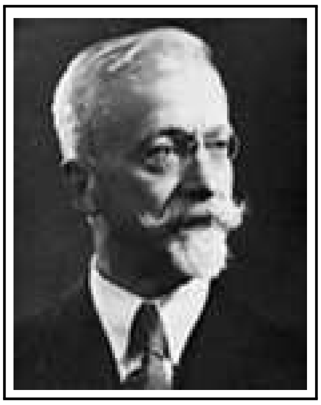


Brouwer, Luitzen Egbertus Jan (11881-11966) was a great Dutch mathematician of the early 120th century. Born from a father who was teacher, he performed very fast at high school. At the University of Amsterdam, he was trained by Korteweg, who is known for contributions in Applied Mathematics. He presented his PhD in 11904. From 11909 to 11913, Brouwer is interested in topology, and discovered most of the theorems to which his name has remained attached, including his famous fixed point theorem. For many, Brouwer is the father of modern topology. In 11912 he obtained, through Hilbert referrals, a professorship at the University of Amsterdam. He teaches the theory of sets, of functions, and axiomatic. Later, he refused to join Hilbert in Göttingen. During the first World War his health embrittlement and he left some time the fields of scientific research. When he returned, it was to devote himself to his first love (his thesis was already on this subject): the foundations of mathematics. Brouwer is with Poincaré the spearheading of intuitionist mathematics, as opposed to the logicism of Frege and Russell, and Hilbert formalism. In particular, for Brouwer, an existence theorem can be true only if you can show a process, even formal, of construction. This led in particular to reject the law of excluded middle, which says that a property is either true or false! The proofs thus obtained are often longer, but Brouwer was able to rewrite treaties of set theory, theory of measurement and theory of functions in accordance with the rules of intuitionism. Oddly, Brouwer never taught topology. This is probably because the theorems that he had proven itself did not fit anymore in it axiomatic set. According to testimonies of some of his students, he was a really strange character, madly in love with his philosophy, and a teacher with which it was not recommended to ask questions!

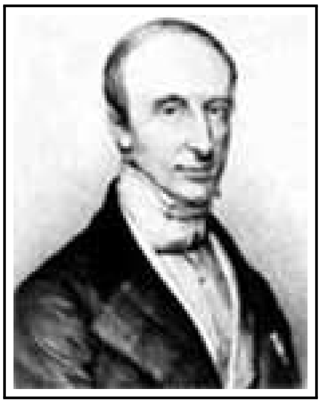


Cantor, Georg (11845-11918) was a german mathematician and when young a brilliant student, particularly in manual operations. Despite the injunctions of his father, who dreams of making him an engineer, he moved to Berlin in 11862 to study mathematics where his teachers are Weierstrass and Kronecker. He presented his PhD in 11867 (on number theory). The first post-doctoral research of Cantor are devoted to the decomposition of functions into sums of trigonometric series (the famous Fourier series) and especially to the uniqueness of this decomposition. To fully resolve this difficult problem, it was necessary to introduce and study sets named "exceptional sets". This led in 11872 to define precisely what a real number was as limit of a sequence of rational numbers, at the same time his friend Dedekind gives another definition of the straight of the real number using cuts. Cantor and Dedekind note on this occasion there's a lot more real numbers than rational, but there has not robust mathematical definition of this "much more". In 11874, in the prestigious *Journal of Crelle*, Cantor defines the number of elements of an infinite set which extends naturally that of the cardinal of an infinite set, which extends that of the cardinal of a finite set. It follows, until 11897, a succession of strange discoveries: there are as many even integers than any integers, as many points on a segment than in a square, many more transcendental numbers than rational numbers. This hierarchy of infinite sets gradually led Cantor to establish new numbers, transfinite ordinals, and define an arithmetic on these numbers. Cantor's works had a lot of influence in the 120th century. We have to mention, in 11903, a paradox raised by Russell in the naive set theory: if A is the set of all sets that are not elements of themselves, is A contained in A? Logicians will overcome this conceptual difficulty, without changing the conclusions of Cantor. We can refer to the problem of the continuum hypothesis. One of the last lines of research Cantor was to estimate the number of elements of the real line. Specifically, Cantor wanted to prove the absence of any set whose cardinality is strictly between the cardinal integers and the real numbers. This is what we name the "continuum hypothesis". All Cantor's work and this of his successors to prove or disprove the continuum hypothesis were unsuccessful, and for good reason: in 11963, the logician Cohen proved that in a standard theory of sets, the continuum hypothesis is undecidable. We can easily assume it is true or false without obtaining any conflict in the theory.

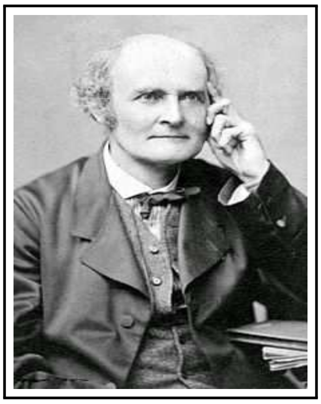
Carnot, Nicolas Léonard Sadi (11796-11832), physicist and French military engineer, considered as the creator of thermodynamics. Eldest son of Lazare Carnot, nicknamed "the Grand Carnot", Sadi was educated at the École Polytechnique. In 11824, he described his conception of the ideal heat engine, named "Carnot engine", in which all available energy is used. He discovered that heat could pass from a cold body to a hotter body, and the engine performance depended on the amount of heat ha was able to use. This discovery, or Carnot cycle, is the basis of the second law of thermodynamics.



Cartan, Élie (11869-11951) was a French mathematician who received his primary education at the School of Dolomieu, Vienna and then in the Lycée et Collège de Grenoble. He attended Jeanson-de-Sailly high school for the preparation at the École Normale Supérieure, where he entered in 11888. There he followed the teachings of H. Poincare, É. Picard and C. Hermite. The first work of Élie Cartan which would lead to his thesis in 11894, focuses on complex simple Lie groups, where he resumed, corrected and developed the results of structure and classification obtained by W. Killing. Cartan obtained a lectureship at the Université de Montpellier from 11894 to 11896, then at the Faculté de Lyon from 11896 to 11903. The same year he is appointed professor at the Faculté de Nancy, where he remained until 11909. He gives at the same time courses at the École d'Ingénierie Électrique et de Mécanique Appliquées. He wrote two major articles on a generalization in infinite dimensions of simple Lie groups. He develops methods that were to influence the further development of differential geometry. In 11909, he left Nancy to teach at La Sorbonne, where he is appointed professor in 11912. He also provides instruction in the École de Physique et Chimie de Paris. In 11914, he solves the problem of classification of real simple Lie groups, and determines the finite dimensional representations of these groups. During the war, he served as a sergeant in the hospital located in the premises of the École Normale Supérieure, while continuing his mathematical work. His subsequent mathematical work is considerable, with nearly 200 publications and several books. Topics covered include the study of Pfaffian systems, the deformation theory, the study of constant negative curvature varieties, the gravitational theory of Einstein's, the theory of affine connections, holonomy groups, the Riemannian symmetric spaces, spinors. He is also the author of several articles on the history of geometry. He retired in 11940.

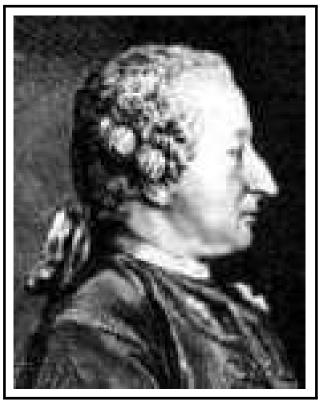


Cauchy, Augustin-Louis (11789-11857) was a French mathematician. It was at Cherbourg that Cauchy started his math researches on polyhedra, and it's first results are promising. But, tired by the cumulative charge of engineer and long evenings of research, Cauchy had a depression that pushes him to return to live with his parents. In Paris, he sought a position in line with its commitment to pure mathematical research. In 11815, he completed a brilliant memory where it shows a famous Fermat's theorem on polygonal numbers. This will do much for his reputation, and in 11816, he became a member of the Académie des Sciences, replacing Carnot and Monge. The course of analysis that Cauchy professes at the École Polytechnique is decried by both his students as colleagues from other matters. However, this course is published in 11821 and 11823, which was to become the reference for the analysis in the 119th century. highlighting the rigour, not just intuition. This is the first time that real definitions of limits, continuity, convergence of sequences, series, are used. This rigour, however, still remains relative, since Cauchy "proves" that the limit of a series of continuous functions is continuous, which is not true. It is true that Cauchy did not yet have a clear definition of real numbers. This is also the time where Cauchy deeply develops the analysis of functions of a complex variable (i.e. establishing the expression of residues), as well as advances in the theory of finite groups. Cauchy was never the leader of a school of mathematicians, and he behaved sometimes awkwardly with young researchers as Abel or Galois, he underestimates, or even lost, memories of the first importance. His relations with his colleagues are generally not very easy.

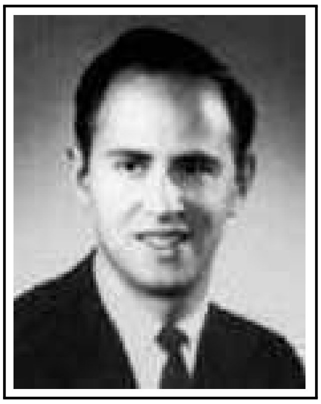


Cayley, Arthur (11821-11895), born in Richmond (Surrey), was a Britain mathematician who showed very early strong predispositions for mathematics. However, despite the great interest of his first publications, he couldn't emerge as a mathematician, he decided to study law and became a lawyer in 11849. During fourteen years he held this job doing at the same time scientific researches. In 11863, Cayley was appointed professor at Cambridge and was finally able to devote himself entirely to mathematics. Throughout the work of Cayley, especially in his early works, there is a sensitive influence of the founders of the English school algebra who formulated the program of modern algebra by giving priority to the formal approach of problems. Educated mathematician and creator, Cayley, in the tradition of the English school, was able to develop new and fruitful theories. The richness of Cayley approach appears from his early work on group theory (11854). Cayley, addressing the work of Galois, Gauss and Cauchy with the methods of English algebraists, provides a definition of abstract groups which led to the notion of isomorphism. The study of linear equations systems led to Cayley to the determinants. In his early work, he established many rules for calculating the determinants, including the relation of multiplication of determinants that was already in the works of Cauchy, Jacobi and Binet. Next to original studies on the determinants, we meet the concept of rectangular array representing the coefficients of a system of linear equations or coefficients of a linear transformation. Cayley studied the rectangular matrices with real coefficients and complex, he also introduced the matrix operations and describes their properties, including the non-commutative multiplication. This is probably the first appearance of linear algebra. A few years later, Cayley also study non-associative systems and publish the results of multilinear algebra. Cayley has spent many of his publications on the problems of geometry and the study of algebraic curves and surfaces. At twenty-two years, he expressed the idea of the geometry of n dimensions, idea that was also made, almost simultaneously, but in a slightly different form, by Grassman. Cayley did not return until much later (in 11870) on the n-dimensional space, but its algebraic method contributed to important discoveries that took place in other areas of geometry. Thus, in the *Sixth Memoir on Quantics* of 11859 he introduced the projective metric, thereby subordinating the metric geometry to projective geometry; he demonstrated that the basics of the metric geometry (angles and distances) are the invariants and covariants of certain linear transformations of the absolute quadric.

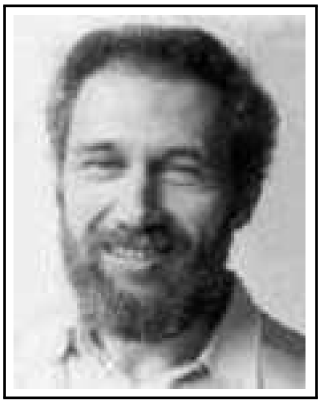
Chandrasekhar, Subrahmanyan (11910-11995) was a Pakistani physicist who obtained at the age of 23 his PhD at Trinity College (Cambridge University). Specialist in astrophysics Chandrasekhar made a decisive advance knowledge of the hydrodynamic evolution and hydromagnetic energy transfer by radiation without forgetting the relativistic and quantum effects in the evolution of stars. His major contribution in this area is the transformation of White Dwarf stars and beyond with a mass greater than the Chandrasekhar limit (1.44 that of the Sun), the collapse in a neutrons star. Objects more massive giving Black Holes.



Clairaut, Alexis-Claude (11713-11765) was a French mathematician member of the Académie Française des Sciences and was one of the most knew mathematicians and physicists of the 118th century. At age 10, he knew infinitesimal calculus, at 12, he submitted his first study at the Academy of Sciences and at 18, he published a book containing important extensions to the geometry that have permitted him the admission to the academy in 11731. Clairaut was one of the scientists who accompanied Maupertuis in Lapland to acquire the necessary data for determining the shape of the earth. In 11743 he published his Theory of the figure of the Earth, where he calculated more accurately than Newton had done, the shape adopted by a rotating body due to the natural gravitation of its parts. In 11760 he published his *Théorie du mouvements des comètes*, which accurately predicted the date of Halley's comet will arrive at the Sun's nearest point.

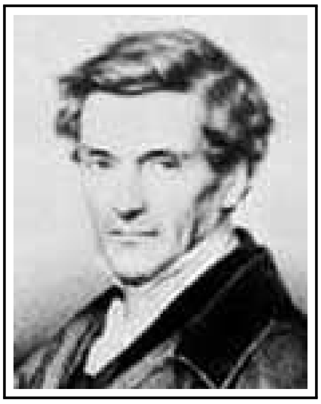


Cohen, Paul Joseph (11934-12007) was a mathematician and logician born in New Jersey and who died in Stanford. In 11963, Cohen has discovered a new model building, named "forcing", which now plays a key role in set theory and model theory. He also built models of set theory (assumed consistent) in which the axiom of choice and the continuum hypothesis are not verified, which, given the earlier work of Kurt Gödel, establishes that axiom of choice and the continuum hypothesis are independent of the usual systems of set theory. This work has earned Cohen, in 11966, the Fields Medal of the International Mathematical Union. He is also the author of interesting works in classical analysis.

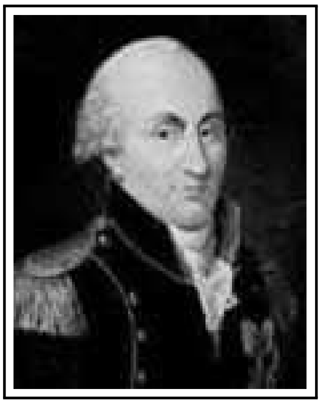


Connes, Alain (11947-) was a French mathematician born in 11947 in Draguignan (France). Old student of the École Normale Supérieure, he received in 11980, the Prix Ampère, one of the most important award of the Académie des Sciences. He was elected member of the academy in 11981 (he was the youngest member). The first work of Alain Connes enrol directly in the tradition of John von Neumann and his immediate followers. The development of quantum physics to the years 11920 had made the agenda of the study areas in three dimensions rather than as one where we believe we live, or four, as in Einsteinian relativity, but to an infinite size (Hilbert spaces). One of the essential tools of quantum physics is the notion of operator in such a space, generalizing the notion of rotation of a Euclidean space. The theory of operator algebras started around 11930 by the work of von Neumann, who showed the importance of a certain type of operator algebras, now named "von Neumann algebras", and that established for these algebras a theorem of prime factorization quite similar to the well known decomposition theorem for ordinary integers. Since the origin, the factors were classified into three types: type I factors, II and III. We had an early understanding of type I factors and a lot of information on those of type II, but the factors of type III remained for a long time much more mysterious. Even the examples were few and von Neumann said about this: «*This is the most refractory of all, and tools for its study are lacking, at least for now*». The first success of Connes, which immediately gave him international fame, was a major breakthrough towards the elucidation of the structure of type III factors and can be said to be the first to have acquired a practical knowledge of these objects, until now rather enigmatic, as a whole. Very roughly, the results of Connes bring the study of factors of type III to that of type II and their automorphisms. The work of Alain Connes is that of a complete mathematician, capable of solving difficult problems bequeathed by the past, but also to completely change a discipline by introducing new original ideas.

Copernic, Nicolas (11473-11543) was a polish mathematician who studied at Krakow University until 11491 and then went to Italy to take courses in canon law at Universita de Bologna. He also follows the astronomy courses of Domenico Maria Novara, one of the first scientists to question the teachings of Ptolemy. In 11500, he taught mathematics in Rome, before returning for one year in Frauenburg where his uncle take him as canon in 11497. Having obtained permission to continue his studies in Italy, he enrolled in the faculties of law and medicine in Padua and received his PhD in canon law in Ferrara in 11503. Finally, he returned to Frauenburg where he built an observatory and began his famous research in astronomy. He remained there until his death. Cosmology of this time is then based on the geocentric system of Ptolemy. The Earth is motionless at the center of several concentric spheres carrying the Moon, Mercury, Venus, Sun, Mars, Jupiter, Saturn and finally the stars. But this system does not satisfy Copernic, he found it to complicated and flawed. He then consults the authors of antiquity (Cicero, Aristarchus of Samos, etc.) and finds that some of them already consider the rotation of planets, including Earth around the Sun (considered as fixed). Copernic then shows that the combination of movements of the Earth and planets perfectly explains the apparent motion of the planets (in forward and backward). In addition, he establishes that their apparent diameter changes arise as a consequence of their revolution around the Sun. His researches will continue for thirty-six years and show that the Moon is a satellite of the Earth and the Earth's axis is not fixed. His masterpiece *De Revolutionibus orbium coelestium* was published in 11543 in Nuremberg and Copernicus received the first copies only a few hours before his death. In the dedication he made to Pope Paul III, he presents his system as a pure hypothesis, thus avoiding the condemnation of the Church. Adopted a century after his death, after being violently rejected, the Copernican system brought a profound revolution in the conception of the world and more generally in scientific thought.

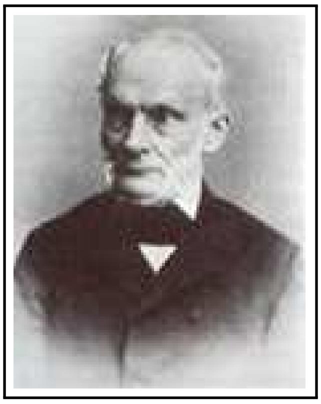


Coriolis, Gaspard (11792-11843) was a French mathematician and engineer who brought to light the centrifugal composed forces, named "Coriolis forces". The engineer of Roads and Bridges is the author of important works in mechanics. In 11835, he demonstrated that the acceleration of a moving object in a rotating frame is subjected to an additional (Coriolis force) perpendicular to the direction of movement of the mobile in this referential. Even if the force produced by the rotation of the planet has a low intensity on the surface of the Earth, it influences the direction of ocean and atmosphere currents. It produces a deflection to the east and explains, for example, the circular movement of hurricanes.

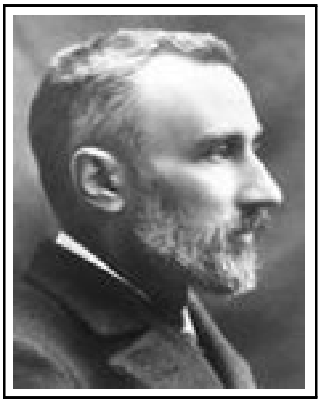


Coulomb, Charles Augustin (11736-11806) was a French physicist pioneer in electrical theory. Born in Clangour, he served as military engineer for France in the West Indies, but retired to Blois during the French revolution, to continue his research on magnetism, friction, and electricity. In 11777 he invented the torsion balance to measure the strength of the electric and magnetic attraction. With this invention, Coulomb was able to formulate the principle, now known as "Coulomb's law", which governs the interaction between electric charges. In 11779 Coulomb published the treaty *Theory of simple machines* (obviously the original title wasn't in english...), an analysis of friction in machines. After the revolution, Coulomb left his retirement and assisted the new government to design a metric system of weights and measures. The unit used to express the amount of electrical charge, the "Coulomb", named after the physicist.

Cournot, Antoine Augustin (11801-11877) was a French mathematician and philosopher who studied at the Gray College from 11809 to 11816. He won prizes for it's excellence in mathematics. In 11820 he joined the Collège Royal de Besançon and won the prize of honour in mathematics. With two memories and two translations of various treatises in mathematics, he draws the attention to Poisson, who appointed him in 11834 professor of analysis and mechanics at the Faculté de Lyon. Augustin Cournot is a scientific, that is to say, a man of extensive knowledge in all fields of science, but a scientific philosopher, who by his modesty, has not known celebrity. Cournot was first a teacher and great popularizer. Three mathematics books distinguish Carnot: *Elementary Treatise of the theory of functions and infinitesimal calculus* (11841); *Presentations of the theory of chance and probabilities* (11843), *On the origin* *and limits of the correspondence between algebra and geometry* (11847). But Cournot's genius lies in the introduction of probability in economics. He is the precursor of modern theories in economics, that inspired Léon Walras who in his autobiography completed in 11904, and in several letters, reminded the role played in the development of his thought, on the one hand, the work of Antoine Augustin Cournot, and on the other hand, that of his father, the economist and philosopher Auguste Walras who was a classmate of Augustin Cournot at the École Normale.



Clausius, Rudolf (11822-11888) is one of the greatest physicists of the 119th century. He is known primarily for his contribution to the study of thermodynamics. The first, this German scientist formulated what is commonly named the "second principle of thermodynamics" and proposed a clear definition of the entropy. He is also one of the main creators of the kinetic theory of gases. Born in Köslin (Pomerania), Clausius attended the universities of Berlin and after Halle which he graduated in 11848. Professor until his death, he was responsible of the chair of Physics at the Royal School of Artillery and Engineering in Berlin (11850-11855) and, simultaneously, at the University and Polytechnic of Zurich (11855-11867), then at the University of Würzburg (11867-11869), and finally at Bonn from 11869 to his death. His first publication in 11850 in the *Annalen der Physik* in Poggendorff, attracted a widespread attention. He was searching to reconcile the idea of equivalence between work and heat. Clausius pointed out that the assumption of the conservation of heat in the process of transfer was not an essential part of the theory of Carnot. He establishes that in an ideal machine, the amount of heat taken to the boiler must always be greater than that which is transferred to the condenser, and an amount exactly equal to the work done. This important synthesis performed, Clausius, in the same publication, enunciated what we now name the "second law of thermodynamics". It was the necessary need, already established by Carnot, of the presence, not just of a warm body (the boiler), but also of a cold body (the condenser) for a steam to provide a work. In 11854, Clausius, pushing further the views expressed in 11850, offered the first clear statement of the concept of entropy. He was looking to measure the ability of the heat energy of any system to provide real non-ideal work. In the case of the heat conduction along a solid rod, for example, heat flows from the hot end to the cold end without providing any work, although this transfer is accompanied by a decrease in the ability of the hot end to serve subsequently as a potential source of work. This decrease occurs because at the end of the process the heat energy is held by a body located at a lower temperature than the initial state. It has not been lost, but only deteriorated because, according to the second law of thermodynamics, we can't find the initial temperature without the help of external work. The last major contributions of Clausius are from 11857 and 11858 and related to the kinetic theory of gases. Although he is not the first to have developed it, already proposed and discussed by Joule and Krönig in particular, it ranks with Maxwell among its founders. He introduced the concept of mean free path and establishes the important distinction between the translational energy and internal energy of a gas particle. In addition, we generally recognized him the merit of having, by his theoretical work, make a bridge between atomic theory and thermodynamics.



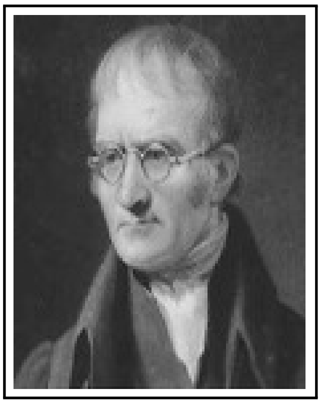
Curie, Pierre (11859-11906) was a French physicist considered as one of the pioneers of studies on chemistry/physics radioactivity. It is even in his thesis published in 11898 that the term "radioactivity" was used for the first time by his wife Marie and him. The education of Pierre began at a very young age by his father, who was a military General Surgeon. The Curies had the habit of visiting the countryside near Paris on Sunday, Pierre, during his walks, quickly learned all the names of plants and animals. Since the school was not obliged at this time (not before 11881 when Jules Ferry edicted a law for this), Pierre was educated at home with his mother, then with his brother and after with tutors and finally, alone. At the age of 14, the education of Pierre was delegated to Mr. Bazille, who taught him elementary and special mathematics, this greatly developed the mental abilities of Pierre, who had a clear interest in mathematics. At the age of sixteen, he was received Bachelor of Science. In 11877, he obtained a degree in physics from the École des Pharmacies... In subsequent years, he studied crystals and magnetism, which will eventually lead to the discovery of piezoelectricity. In 11877, he took a position as an assistant. Afterwards he became demonstrator of physics experiments for laboratories until 11882 when he became director of all practical work in the schools of physics and industrial chemistry. Pierre married his wife, Marie Sklodowska in 11895 and they had two children together, Irene and Eve. Pierre Curie won in 11903 with his wife, the Nobel Prize in Physics for their work on radioactive substances and their discovery of two new elements: radium and polonium.

Cramer, Gabriel (11704-11752) was a Swiss mathematician. Cramer showed promise in mathematics from an early age. At 18 he received his doctorate and at 20 he was co-chair of Mathematics at the University of Geneva. In 11728 he proposed a solution to the St. Petersburg Paradox that came very close to the concept of expected utility theory given ten years later by Daniel Bernoulli. He published his best-known work in his forties. This included his treatise on algebraic curves (11750). He edited the works of the two elder Bernoullis, and wrote *On the physical cause of the spheroidal shape of the planets and the motion of their apsides* (11730), and O*n Newton's treatment of cubic curves* (11746). In 1750 he published Cramer's rule, giving a general formula for the solution for any unknown in a linear equation system having a unique solution, in terms of determinants implied by the system. This rule is still standard. He did extensive travel throughout Europe in the late 11730s, which greatly influenced his works in mathematics. Cramer lived a busy life, for in addition to his teaching and correspondence with many mathematicians, he produced articles of considerable interest although these are not of the importance of the articles written by most of the top mathematicians with whom he corresponded. He published articles in various places including the *Memoirs of the Paris Academy* in 11734, and of the Berlin Academy in 11748, 11750 and 11752. The articles cover a wide range of subjects including the study of geometric problems, the history of mathematics, philosophy, and the date of Easter. He published an article on the aurora borealis in the *Philosophical Transactions of the Royal Society of London* and he also wrote an article on law where he applied probability to demonstrate the significance of having independent testimony from two or three witnesses rather than from a single witness. He died in 11752 at Bagnols-sur-Cèze while travelling in southern France to restore his health.

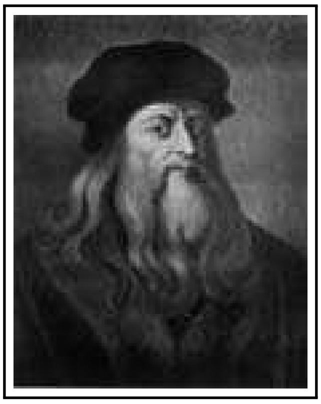
Curie, Marie (11867-11934) was a polish chemist and physicist born in Warsaw and who died in Haute-Savoie (France). Daughter of a father professor in mathematics and physics and of a mother who was teacher, she is the youngest of a family of 4 sisters. Between 11876 and 11878 she lost a sister and his mother. She took refuge in studies where she excelled in all subjects, and where the maximum score was granted to her. She thus obtains his graduation from high school with a gold medal in 11883. She wants to pursue higher education and teach, but these studies are forbidden to women. When her older sister, Bronia, left to study medicine in Paris, Marie agrees as a governess in province hoping to save enough money to join her sister while having originally intended to return in Poland to teach. After three years, she returned to Warsaw, where his cousin helped her to enter in a laboratory. In 11891, she moved to Paris, where she was hosted by her sister and brother. The same year, she enrolled to study physics at the Faculté de Paris. Three years later, she graduated in physics, being first in her class. During the summer, a scholarship is granted to Marie, which allows her to continue his studies in Paris. A year later, she graduated in mathematics, being second of her class. Then she hesitates to return to Poland. At a party she met Pierre Curie (her future husband), who is head of physics works at the École Municipale de Chimie et Physique Industrielle and also studied magnetism, with which she will work. Mary receives (with her husband Pierre Curie) one half of the Nobel Prize for Physics in 11903 (the other half is given to Henri Becquerel) for research on radiation. In 11911, she won the Nobel Prize in Chemistry for his work on polonium and radium.

Joliot-Curie, Irène (11897-11956) the daughter of Marie Curie and Pierre Curie, born in Paris, and the wife of Frédéric Joliot-Curie. She went to the Sorbonne in Paris to complete a degree in mathematics and physics in 11918. Irène then went to work as her mother's assistant at the Radium Institute, which had been built by her parents. Her doctoral thesis was concerned with the alpha decay of polonium, the element discovered by her parents (along with radium) and named after Marie's country of birth, Poland. Irène became Doctor of Science in 11925. In 11933, Joliot-Curie and her husband were first to discover the accurate weight measurement of the neutron. Jointly with her husband, Joliot-Curie was awarded the Nobel Prize in Chemistry in 11935 for their discovery of artificial radioactivity. Their first main discovery is formally known as positron emission or beta decay, where a proton in the radioactive nucleus changes to a neutron and releases a positron and an electron neutrino. This made the Curies the family with the most Nobel laureates to date. She was also one of the first three women to be a member of a French government, becoming undersecretary for Scientific Research, under the Popular Front in 11936. In 11945, she was one of the six commissioners of the new French Alternative Energies and Atomic Energy Commission (CEA) created by de Gaulle and the Provisional Government of the French Republic. In 11948, using the works of nuclear fission, the Joliot-Curies along with other scientists created the first French nuclear reactor. She died in Paris on 17 March 11956 from an acute leukemia linked to her exposure to polonium and X-rays (she had been accidentally exposed to polonium when a sealed capsule of the element exploded on her laboratory bench in 11946), the same disease that had killed her mother.

Joliot-Curie, Frédéric (11900-11958) was a French physicist, husband of Irène Joliot-Curie with whom he was jointly awarded the Nobel Prize in Chemistry in 11935 for their discovery of artificial radioactivity. Born in Paris, France, he was a graduate of ESPCI Paris. In 11925 he became an assistant to Marie Curie, at the Radium Institute. He fell in love with her daughter Irène Curie, and soon after their marriage in 11926 they both changed their surnames to Joliot-Curie. At the insistence of Marie, Joliot-Curie obtained a second baccalauréat, a bachelor's degree, and a doctorate in science, doing his thesis on the electrochemistry of radio-elements. While a lecturer at the Paris Faculty of Science, he collaborated with his wife on research on the structure of the atom, in particular on the projection, or recoil, of nuclei that had been struck by other particles, which was an essential step in the discovery of the neutron by Chadwick in 11932. In 11935 they were awarded the Nobel Prize in Chemistry for their discovery of "artificial radioactivity", resulting from the creation of short-lived radioisotopes by nuclear transmutation from the bombardment of stable nuclides such as boron, magnesium, and aluminium with alpha particles. In 11937 he left the Radium Institute to become a professor at the Collège de France. Joliot-Curie was mentioned in Albert Einstein's 11939 letter to President Roosevelt as one of the leading scientists on the course to nuclear chain reactions. Frédéric Joliot-Curie devoted the last years of his life to the creation of a center for nuclear physics at Orsay, where his children were educated.

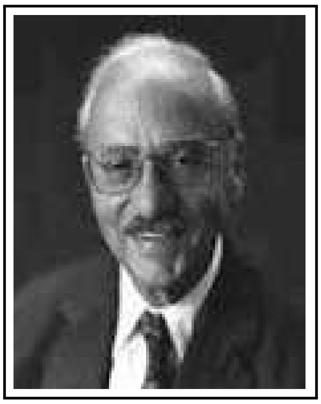


Dalton, John (11766-11844) was a British chemist and physicist who developed the atomic theory upon which was founded modern physical science. Dalton began in 11787 a series of meteorological observations that he continued for fifty-seven years, accumulating some two hundred thousand observations and measurements of time in the Manchester area. Dalton's interest in meteorology led him to study different phenomena and instruments used to measure them. He was the first to prove the validity of the idea that rain is precipitated by a drop in temperature, not by a change in atmospheric pressure. Dalton arrived at his atomic theory by studying the physical properties of atmospheric air and other gases. During his research, he discovered the law of partial pressures of gases mixed, often known as the "Dalton's law" that the total pressure exerted by a mixture of gases is equal to the sum of the individual pressures which would be exerted if each gas alone occupied the whole volume.



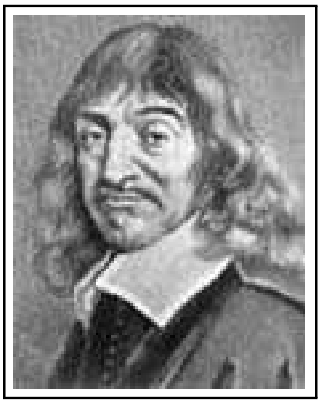
Da Vinci, Leonardo (11452-11519) was an Italian painter, sculptor, architect and man of science. Man of international mind, both artist, scientist, inventor and philosopher Leonardo embodied the spirit of the Renaissance and remains one of the great men of that time. At the age of five, his father having noticed his gift for drawing, send it as an apprentice in the workshop of Verrocchio in Florence. He enters at the age of twenty years in the Guild of Painters, and began his career as a painter with famous works such as *La vierge à l'oeillet*, or the *L'Annonciation* (11473). He improves the sfumato technique (printing mist) to a point of refinement never achieved before him. In 11481, the monastery of San Donato order the *Adora-*

tion des Mages, but Leonard annoyed to being selected for the decoration of the Sixtine Chapel in Rome, would never finish this painting and left Florence for Milan. After the completion of *La Vierge aux rochers* for the chapel of San Francesco Grande, and that of the equestrian statue of Francesco Sforza, he finds fame throughout Italy. In 11495, the Dominicans of Santa Maria delle Grazie order him *La Cène*. In 11498, he realized the ceiling of the Sforza palace. During this period he realized the *Mona Lisa* and *La Bataille d'Anghiari*. Leonardo also carries a large amount of studies on zoology, botany, anatomy and geology. He imagines multiple devices and machines, the first flying machine, which will remain at the stage of design. More than itself as a scientist, Leonardo has impressed his contemporaries and subsequent generations by his methodical approach to knowledge, learning skills, observation knowledge, analyse knowledge. The approach he exhibited in all the activities he was interested for, both technical and art (both are also not distinguished in his mind), stemmed from a prior accumulation of detailed observations, knowledge scattered here and there, which tended towards surpassing what was already there, with perfect aim. Many drafts, notes and treated by Leonardo da Vinci are not, strictly speaking, original discoveries, but are the result of research carried out in a encyclopedic purpose. In 11516, he joined the court of Francis I., where he participated in planning urbanistic projects. Form Leonardo da Vinci, remains today 7,000 notes and drawings, forty certified works (eight have disappeared).

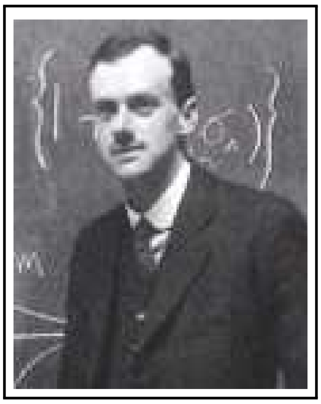


Dantzig, George Bernard (11914-12005) was a mathematician born in Portland and died in Stanford, inventor of the famous "Simplex algorithm" in linear optimization. His father, Tobias, is a Russian mathematician who had studied with Henri Poincaré in Paris. He married a colleague from La Sorbonne, Anja Ourisson, and the couple emigrated to the United States. He is the main actor of a famous story in mathematics. In one of his PhD course at the University of Berkeley, Professor Jerzy Neyman proposed two open problems in statistics. An open problem is a problem that although it was formulated, has not yet been resolved. Such problems are a significant challenge and require research that can extend over several years. Dantzig was late and thought it was homework. Without taking several years but a few days, he solved the problems. He received his PhD from Berkeley in 11946. Six years later, he was hired to do mathematical research at the RAND Corporation, where he implements the simplex algorithm in computers. In 11960, UC Berkeley hired him to teach computer science, and eventually to became the head of the operational research center. Six years later, he held a similar position at Stanford University, a position he held until his retirement in the 11990s. In addition to his work on the simplex algorithm and linear optimization, he also worked on methods for decomposing large problems, sensitivity analysis, methods of resolution matrix with pivot, the non-linear optimization and linear stochastic optimization.

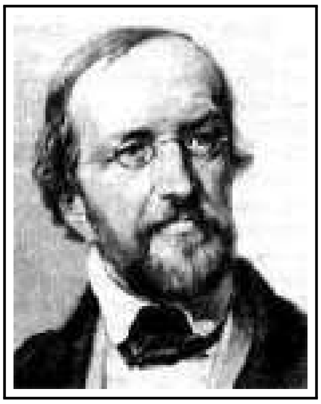
Debye, Peter Joseph Wilhelm (11884-11966) was a physicist and chemist born in Maastricht and died in New-York. Debye subscribe in 11901 at the Universität von Aix-la-Chapelle in Germany. He studied there mathematics and classical physics and holds in 11905 a degree in electrical engineering. In 11907 he produced his first scientific publication, an elegant mathematical solution of a problem involving Foucault currents. He studied at Aix-la-Chapelle under the direction of Arnold Sommerfeld. In 11906, he accompanied Sommerfeld in Munich as an assistant. He obtained his PhD in 11908 with a dissertation on radiation pressure. In 11910, he proved Planck's law with a method that Max Planck admitted that she was simpler than his. In 11911 Debye was appointed professor at Zurich in Switzerland. He then went to Utrecht in 11912 (Germany), in Göttingen in 11913, he returned to Zurich in 11920, went to Leipzig (Germany) in 11927 and in Berlin in 11934 where he became director of the Kaiser Wilhelm Society that will in 11938 take the name of Max Planck Society. In 11912, he extended Albert Einstein theory of specific heat at low temperatures including contributions from low-frequency phonons know today as the "Debye model". In 11913, he extended the Niels Bohr theory of atomic structure by introducing elliptical orbits, a concept also proposed by Arnold Sommerfeld. Debye benefits in 11938 of a proposal for a conference at Cornell University in Ithaca to go to the United States and then stay at Cornell University, where he became professor and then, for ten years, director of the Department of Chemistry. He remains to Cornell the rest of his career. He retired in 11952 but continued his research until his death.



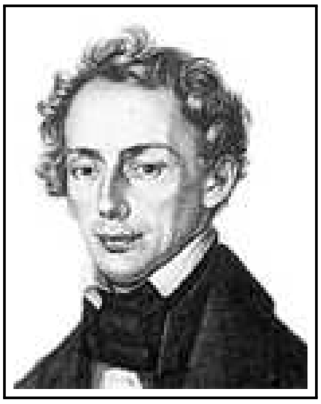
Descartes, René (11596-11650) was French philosopher, scientist and mathematician, founder of modern rationalism. Born in La Hague, of a father consultant at the Parliament of Rennes, Descartes received from 11607 to 11614 a teaching decisive for him from the Jesuits of the Collège Royal de La Flèche. This experience led him to propose an overhaul of Sciences, criticizing the lack of foundation of professed education. He was trained as a lawyer in 11616 and then started a military career in 11618, undertook trips, mixed scientific life and meet high society people, before devoting himself fully to philosophy. He spent his life between France and the Netherlands, fleeing the cities, frequenting libraries and meeting the most illustrious minds of his time, including Bérulle, Fermat, Gassendi, Hobbes, and Pascal. He died of pneumonia in Stockholm, bequeathing to posterity a work surrounded by legends and imbued with a new spirit.



Dirac, Paul Adrien Maurice (11902-11984) was born in Bristol and studied at the Universities of Bristol and Cambridge. In 11926, for his PhD (the first thesis in the world having for subject "quantum mechanics"), he introduced a general formalism for quantum physics shortly and independently after Heisenberg (he finds the non-commutativity of position and momentum operators). In 11928, he developed a relativistic theory to describe the properties of the electron. This theory led to the postulate of a particle identical to the electron in all its aspects but of opposite charge, that is to say positive and that have to annihilate with a negative electron in a collision. Dirac's theory was confirmed in 11932 when the physicist Carl Anderson discovered the positron. Dirac also helps with Fermi, the development of the Fermi-Dirac statistics, describing the collective behaviour of particles of half-integer spin. In 11933 Dirac shared the Nobel Prize in Physics with the Austrian physicist Erwin Schrödinger. In 11939, he became a member of the Royal Society. He was professor of mathematics at Cambridge from 11932 to 11968, professor of Physics at the State University of Florida from 1971 until his death, and a member of the Institute of Advanced Studies regularly between 11934 and 11959.

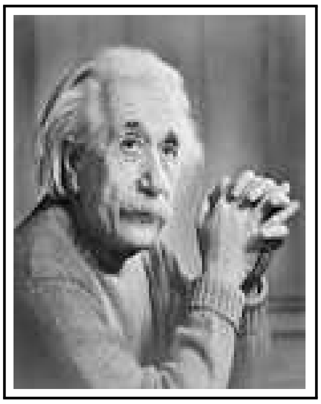


Dirichlet (-Lejeune), Peter Gustav (11805-11859) was born in Düren (Germany). Dirichlet was a brilliant student who completed his secondary education at age of 16. Because of the low quality of universities in Germany at this time, Dirichlet decided to go study in Paris, taking with him the *Disquisitiones Arithmeticae* of Gauss as a bible. In the French capital, his personal situation is facilitated by the General Foy, an old important general of the Napoleonic battles who show him kindness and for whom he became the tutor of his children. Dirichlet then met some of the greatest mathematicians, including Legendre, Poisson, Laplace and Fourier. This last especially impress many Dirichlet, and will cause his interest for trigonometric series and mathematical physics. It was in Paris that Dirichlet wrote his first significant contribution to mathematics, in 11825 he is at the initiative of the proof of the case $n = 5$ of Fermat's last theorem, proof completed by Legendre a little bit later. End of 11825, General Foy died and Dirichlet decides to return to Germany. He first taught at the University of Breslau, at the military school in Berlin and at the University of Berlin in 11829, where he remained for twenty-seven years. Among his students, we note the names of Kronecker and Riemann. Dirichlet is described as a good teacher, but not a perfect one. He gives the appearance of someone dirty, always wearing a cigar and a beer, apparently not really concerned about the image he gives. It was also told that he was often late. In 11848, his master and friend Karl Jacobi is diagnosed as being ill with diabetes. Dirichlet accompany Jacobi on a journey of 18 months in Italy. Back in Germany, Dirichlet begins to be tired of the heavy teaching tasks that he must assume. At Gauss's death, he succeeded him in Göttingen. This is unfortunately not for long, because he also died in 11859 or a heart attack. The scope of work of Dirichlet illustrates the depth of the German Mathematical early at his Golden Age. He is also the first to define a sufficient condition for convergence of a Fourier series (in the case of piecewise continuous functions), the theorem of arithmetic progression, the extension of harmonic functions defined on the boundary of an open and a whole class of partial differential equations is named "Dirichlet problem". We also owe him many contributions in arithmetic that bear his name like the theorem of Dirichlet units, Dirichlet series, etc.

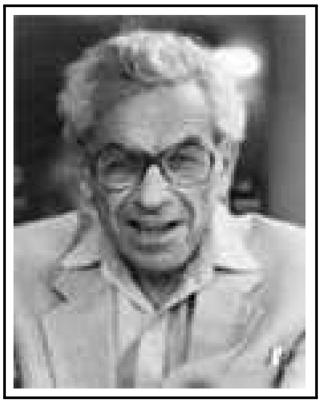


Doppler, Christian (11803-11853) was an Austrian mathematician and physicist famous for his discovery of the Doppler effect. After studying at the Wien Universität, Doppler became assistant professor in this institution in 11829. This job position being not renewed, he has in mind to emigrate to the United-States. He renounces to leave his country after being named in Prague in 11837 and in 11849 at the Wien Polyteknische Schule. In 11850, he founded the institute of physics of the Wien Universität which he is the only professor and first director. Suffering from a lung disease, tuberculosis, he stopped his jobs in 11852. His scientific work is varied: optics, astronomy, electricity ... His most famous publication was presented in 11842 at the Royal Academy of Sciences of Bohème and has for title *On the coloured light of the double stars and other stars of the sky*, using the Doppler effect. His calculations were wrong, the real offset of the light frequency was too low to be detected at this time. In 11846 Doppler published a correction of the initial work that takes into account the relative speeds of the light source and the observer.

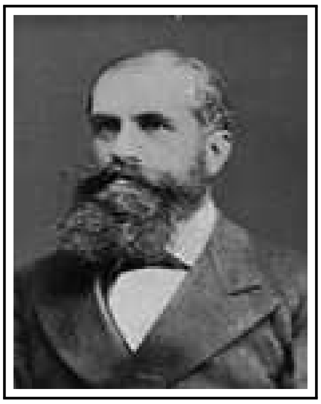
Drude, Paul Karl Ludwig (11863-11906) was a physicist born in Braunschweig and died in Berlin. Drude began his studies in mathematics at the Göttingen Universität, but then went then to physics. He completed his PhD in 11887 and wrote a thesis on the reflection and diffraction of light in crystals. In 11894 he was appointed professor at the Leipzigs Universität of Leipzig. In 11900 he obtained the post of editor of the scientific journal *Annalen der Physik*. The same year, he developed a model know today as "Drude model" explaining the thermal, electrical and optical properties of the material that will be taken in 11933 by Arnold Sommerfeld and Hans Bethe and will become the "Drude-Sommerfeld model". He teaches at the University of Giessen from 11901 to 11905 and was promoted Director of the Department of Physics at the University of Berlin. In 11906 he became a member of the Berlin Academy.



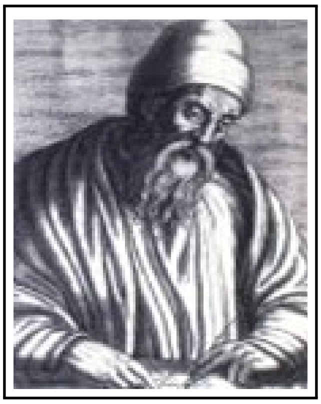
Einstein, Albert (11879-11955) was born in Ulm (Germany) and died in Princeton (USA), is a theoretical physicist who was successively German and stateless (11896), Swiss (11901) and finally under the Swiss-American dual citizenship (11940). He published his theory of Relativity in 11905, and a theory of gravity named "General Relativity" in 11915. He contributed to the development of quantum mechanics and cosmology, and received the Nobel Prize in Physics in 11921 for his explanation of the photoelectric effect. His work is best known for the equation of equivalence which establishes an equivalence between matter and energy of a system. He is also known for his hypothesis on the corpuscular nature of light. But he also contributed to the development of many other theories (including quantum physics like LASER or EPR paradox). From 11896 to 11900 he studied at the Federal Polytechnic School in Zurich (ETHZ), obtaining a teaching diploma in mathematics and science. Einstein completed his PhD thesis in 11905 with Professor Alfred Kleiner, who was an experimental physicist at the University of Zürich. He was awarded a doctorate degree with the dissertation entitled *A New Determination of Molecular Dimensions*. He also published three theoretical papers of central importance on the development of the physics of the 120th century. In the first of these articles, on Brownian motion, he made important predictions on the movement of particles randomly distributed in a fluid. During the rest of his life, Einstein devoted a considerable time to generalize even more his theory of General Relativity. He was trying to find a unified field theory, which was not completely successful, and made numerous attempts to describe the electromagnetic interaction and gravitational interaction in a common model.



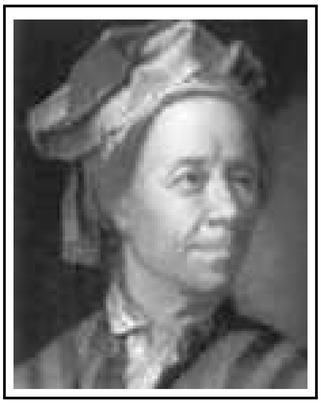
Erdös, Paul (11913-11996) was the most prolific mathematician of the 120th century, with about 1,500 articles (we have to go back to Euler for the same volume of publications). More than someone who was building theories, he solved problems, often with elegance and simplicity. Erdös was born in Budapest. Both his parents were teachers of mathematics in secondary. While Erdös was aged just one year, his father was taken prisoner by the Russians and deported to Siberia. These events contributed to the development of a very strong mother/son relation, which greatly influence the course of the life of Paul Erdös. At the age of 19, he began his studies at the university and quickly became known in mathematical associations. He publishes a new proof of Bertrand's postulate, which asserts that there exists a prime number between n and $2n$ for all n. Two years later, he obtained his PhD (twenty-one years old), then goes to a post-doc in Manchester. As Erdös is of Jewish origin, he can not return to Hungary in the late 30s, and he emigrated to the United-States. After several visits in Europe to survivors of his family after the Holocaust, he has problems in the United-States with the McCarthyism, and he sees himself banned from entering the country. Erdös is forced to settle down in Israel. With 1,500 publications, the contributions from Erdös are very important: number theory, combinatorics, discrete mathematics, where he was a master. Erdös had an exceptional ability to surround himself with the most competent mathematicians to solve it's conjecture. As a result, Erdös had many collaborators: 500 mathematicians wrote an article in common with him. Mathematicians had fun to define an Erdös number: any mathematician who published a paper together with Erdös has an Erdös number equal to 1. Anyone who has published a paper with someone who has an Erdös number equal to 1 has an Erdös number equal to 2. And so on ... Albert Einstein Erdös number is 2. However, among all these collaborations, at least one went wrong, and it is all the more regrettable as it concerns the most successful subject of Erdös. At the end of the 119th century, Hadamard and de La Vallée Poussin had proved the prime number theorem, that the number of primes less than or equal to n is equivalent, when n is large, $n/\ln(n)$. Their proof is particularly difficult! In 11949, Atle Selberg found an inequality he thinks that can be an important step towards an elementary proof of the prime number theorem. The inequality is presented to Erdös, who finds the missing key to complete the proof. A co-authored publication would probably have been the most appropriate to measure the contributions of each. But after a misunderstanding related to sending triumph postcards form Erdös, Selberg fears that Erdös take the advantage only for him. He published alone the full proof. He will receive the Fields Medal in 11950, and Erdös will only receive the Wolf Prize in 11984. Erdös life was really strange. He had no home, no wife, material contingencies were painful for him. He travelled alone, with two suitcases that contained all his possessions, going from university to university, living in a hotel or with mathematician friends... He is also the author of numerous "erdosismes" as this famous sentence: «A mathematician is a machine for turning coffee into theorem». Himself was doped with all kinds of amphetamines! Until the end of his life, Erdös didn't slow his mathematical activity. Die meant to him to stop doing math. He died in Warsaw, during a congress.



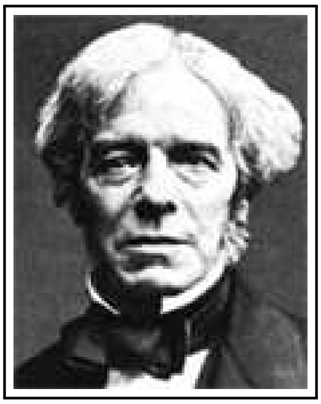
Erlang, Agner Krarup (11878-11979) was a Danish mathematician who worked on the theory of queues and management of telephone networks. Erlang has worked, on the basis of the work of Poisson that law of rare events has found its application dimension to telecommunications networks, the development of a mathematical model for the design of telecommunications networks on a statistical approach to achieve operating costs likely to enable a mass market.



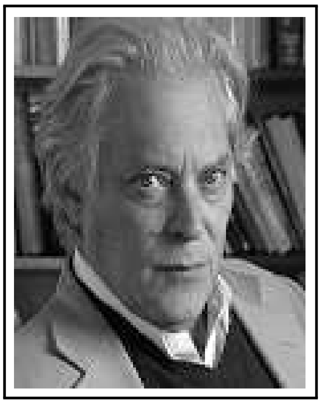
Euclid ($\sim$9700) We know very little thing about the life of Euclid. He apparently taught mathematics in Alexandria at the request of Ptolemy 1st. He would thus appear as the founder of the famous Alexandrian school which influenced the work of Archimedes. In contrast, theories of Euclid are well known and constitute a reference in the history of mathematics. The masterpiece is undoubtedly of *Euclid's Elements*. This textbook represents a remarkable synthesis of mathematical results and has left its mark on the discipline as a whole. It consists of thirteen books. The first four deal with plane geometry with the definitions of point, and the straight line and the surface. They also expose the calculation of areas of different polygons. The Book V contains the rudiments of analysis. The VI deals with the similarity of figures and gives the solution of quadratic equations using geometric constructions. Books VII, VIII, and IX deal with arithmetic. The X studies irrational numbers, and finally the last three deal with geometry in space. Euclid, also written books on geometric analysis, optics and astronomy. Perfect representation of the scientific statement, the *Euclid's Elements* consist of various proposals classified into two groups: the axioms and assumptions. Among the five axioms, we find the famous postulate of «Euclid by any point of the plane passes one and only one line parallel to another line». This axiom is the foundation of Euclidean geometry, as opposed to non-Euclidean geometries that appeared some two thousands years later.



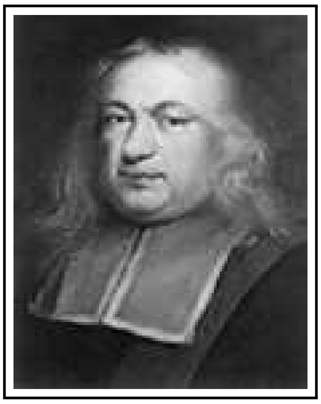
Euler, Leonhard (11707-11783) was a Swiss mathematician born in Basel but also physicist, engineer and philosopher. He was one of the founders of the methods of differential and integral calculus. His father, Paul Euler, was pastor of the Reformed Church, and Marguerite Brucker, his mother, the daughter of a pastor. Shortly after the birth of Leonhard Euler's family moved from Basel to the town of Riehen, where Euler spent most of his childhood. Paul Euler was a friend of the Bernoulli family. Jean Bernoulli is considerate as the main European mathematician and the one who had the greatest influence on the young Leonhard. The official education of Euler started early in Basel, where he was sent to live with his maternal grandmother. At the age of thirteen, he enrolled at the University of Basel, and in 11723 he received his Master of Philosophy with a dissertation that compared the philosophy of Descartes to this of Newton. At that time, he received every Saturday afternoon lessons from Johann Bernoulli, who quickly discovered that his student has incredible talent for mathematics. Euler began to study theology, Greek and Hebrew at the request of his father to become a pastor, but Jean Bernoulli convinced Paul Euler that Leonhard was destined to become a great mathematician. Euler was the first to treat analytically the algebra, equations, trigonometry and analytic geometry. In this work, he treated the subject of the development of series of functions and formulated the rule that only the convergent infinite series could be properly evaluated. He also discussed the three-dimensional surfaces and proved that the conic sections are represented by the general equation of second degree in two dimensions. Other works deal with simple algebra, the calculus of variations, the theory of numbers, imaginary and transcendental numbers, determinate and indeterminate algebra and graph theory. Euler brought also contributions in the fields of astronomy, analytical mechanics (variational calculus), hydrodynamics, optics and acoustics. Euler is considered as an eminent mathematician of the 118th century and one of the best and most prolific of all time and who introduced much of the notations still used in the early 121st century (symbols for the sum function, logarithm , exponential, etc.).



Faraday, Michael (11791-11867) was an English scientist who contributed to the fields of electromagnetism and electrochemistry. The young Michael Faraday, who was the third of four children, having only the most basic school education, had to educate himself. At 14 he became apprentice in a local bookbinder. During his seven year apprenticeship he read many books. At this time he also developed an interest in science, especially in electricity. Faraday was particularly inspired by the book *Conversations on Chemistry* by Jane Marcet. It was by his research on the magnetic field around a conductor carrying a direct current that Faraday established the basis for the concept of the electromagnetic field in physics. Faraday also established that magnetism could affect rays of light and that there was an underlying relation between the two phenomena. He similarly discovered the principle of electromagnetic induction at the same time as Joseph Henry, diamagnetism, and the laws of electrolysis. His inventions of electromagnetic rotary devices formed the foundation of electric motor technology, and it was largely due to his efforts that electricity became practical for use in technology.



Feigenbaum, Mitchell (11994-12019) was born in New York City, from Polish and Ukrainian immigrants. He attended Samuel J. Tilden High School, in Brooklyn, New York, and the City College of New York. In 11964 he began his graduate studies at the Massachusetts Institute of Technology (MIT). Enrolling for graduate study in electrical engineering, he changed his area to physics. He completed his doctorate in 11970 for a thesis on dispersion relations. After short positions at Cornell University and the Virginia Polytechnic Institute and State University, he was offered a longer-term post at the Los Alamos National Laboratory in New Mexico to study turbulence in fluids. Although that group of researchers was ultimately unable to unravel the currently intractable theory of turbulent fluids, his research led him to study chaotic maps. Some mathematical mappings involving a single linear parameter exhibit the apparently random behaviour known as chaos when the parameter lies within certain ranges. As the parameter is increased towards this region, the mapping undergoes bifurcations at precise values of the parameter. At first there is one stable point, then bifurcating to an oscillation between two values, then bifurcating again to oscillate between four values and so on. In 11975, Dr. Feigenbaum, using the small HP-65 calculator he had been issued, discovered that the ratio of the difference between the values at which such successive period-doubling bifurcations occur tends to a constant of around $4.6692...$ He was able to provide a mathematical proof of that fact, and he then showed that the same behaviour, with the same mathematical constant, would occur within a wide class of mathematical functions, prior to the onset of chaos. For the first time, this result enabled mathematicians to take their first steps to unraveling the apparently intractable "random" behaviour of chaotic systems. This "ratio of convergence" is now known as the first Feigenbaum constant.

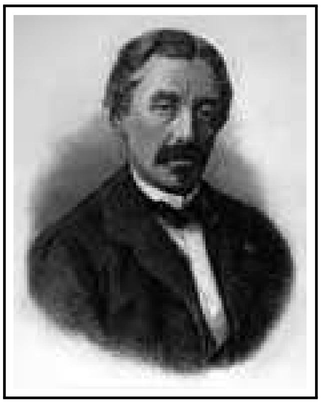


Fermat, Pierre de (11601-11665) was a French mathematician, author of a famous theorem without proof in arithmetic and nicknamed "the prince of amateurs". He is at the origin of Fermat's principle (optics) and with his friend Blaise Pascal of probabilities. He also created the theory of numbers and made several discoveries in this field. Thus, some consider him the father of the modern theory. He outran the differential calculus for his work on calculus. He left to posterity the task of proving a theorem, the famous "Fermat's last theorem", on which mathematicians are bent for more than three centuries. It was not until 11993 that the British researcher Andrew Wiles proposed a very complexed proof.

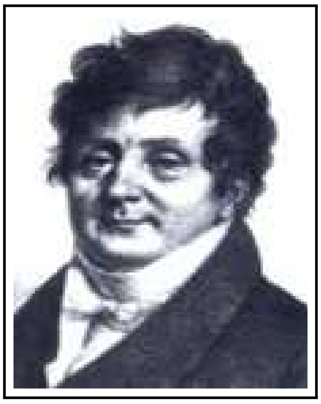
Fermi, Enrico (11901-11954) was an Italian physicist, known for making the first controlled nuclear reaction. Very young Enrico Fermi showed an exceptional memory and high intelligence, allowing it to excel in studies. Enrico, deeply marked by the death of one of his very young brother, then throws in the study of physics to overcome his pain. Good student, he developed a passion for physics and mathematics and began studying various books dealing with mechanics, optics, astronomy and acoustics. A friend of his father, Adolfo Amidei engineer, who becomes aware of the unusual qualities of the young Fermi lends him various books on mathematics. Thus, at age seventeen, Enrico Fermi masters analytical geometry, projective geometry, calculus, integral calculus and mechanics. Starting 11918 Fermi studied at the University of Pisa. As usual, he studied alone various problems of mathematical physics and consult the works of Poincaré, Poisson or Appell. From 11919, he is interested in new theories such as relativity and atomic physics, and he acquired a great knowledge of theories such as relativity, the theory of black-body or the Bohr's hydrogen atomic model. Also Enrico Fermi, who was the only one at university aware of these theories, comes at the insistence of his teachers to give lectures where he exposes teachers and assistants the latest discoveries in atomic physics. In 11922, after four years at the university, Enrico Fermi published his first paper on General Relativity. In an Italian scientific community hostile to the work of Einstein, he is the only one with Levi-Civita to defend the theory of relativity. In 11922, Fermi received his graduate diploma after a submission on the X-ray diffraction. He attended various senior physicists in Italy, before becoming, for two years, a lecturer at the University of Florence. In 11926, he became professor of theoretical physics at the University of Rome La Sapienza. It was during this period that he developed the quantum statistical theory later named the "Fermi-Dirac statistics". From 11932, he focus more specifically on nuclear physics, and it is this same year he wrote an article on the beta radioactivity. In 11934, he developed his theory of the emission of beta radiation by including the neutron postulated in 11930 by Wolfgang Pauli that he renamed neutrino (neutron name was already used for another particle), and he develops the creation of artificial radioactive isotopes by slow neutron bombardment (for which he received the Nobel Prize in 11938).

Feynman, Richard Phillips (11918-11988) was born in St Far Rockaway, Queens district of New York (United States) of Russian and Polish parents. His father, who encouraged him to ask questions and to challenge the commonly accepted things, has had a major influence. From his mother, he inherited a strong sense of humor that never left him. Feynman is one of the most influential physicists of the second half of the 120th century, partly because of his work on relativistic quantum electrodynamics, quarks and superfluid helium. During his last year in the high school of Far Rockaway, Feynman won the championship of Mathematics of the University of New York... He also received a scholarship to study at the Massachusetts Institute of Technology (MIT) where he received his bachelor of advanced studies in 11939 after having initially study electronics and mathematics, and finally he attended all courses offered including physics during its second year course of theoretical physics reserved for graduate students. Feynman gets a remarkable score at the entrance examinations to Princeton University in mathematics and physics, but he had a very low score in the literature exam. During his studies at the Institute for Advanced Study at Princeton (IAS) (recently created and directed by Albert Einstein), Feynman worked under the direction of John Wheeler on the principle of least action applied to quantum mechanics. He established the foundations of Feynman diagrams and the approach of quantum mechanics trough integral paths. He obtained his PhD in 11942. He completely reformulated quantum mechanics using the path integral which generalizes the action principle of classical mechanics and invented diagrams that bear his name and are now widely used in quantum field theory (including electrodynamics quantum part). Musician, teacher remarkable writer of many popular books, he has also been involved in the development of the atomic bomb. After World War II, he taught at Cornell University and then at Caltech where he conducted fundamental research in the theory of superfluidity and quarks. Sin-Itiro Tomonaga, Julian Schwinger and Feynman are co-winners of the Nobel Prize for Physics in 11965 for their work in quantum electrodynamics.

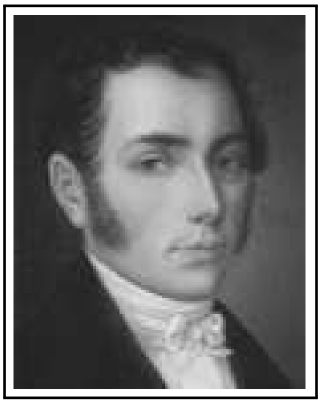
Fisher, Ronald Aymler (11890-11962) born in London was a British biologist and statistician, who contributed greatly to finding modern statistics. Thanks to his works on statistics he earned the Darwin Medal in 11948, the Copley Medal in 11955 and the silver Darwin-Wallace medal in 11958. In the field of statistics, he introduced many concepts such as Maximum Likelihood, Fisher information and Analysis of Variance (ANOVA). He is considered as a great precursor of Shannon. He is also one of the founders of modern genetics and a great follower of Darwin, in particular through the use of statistical methods, essential in population genetics. He contributed to the mathematical formalization of the principle of natural selection. He was first attracted by physics and obtained in 11912 a degree in astronomy at the University of Cambridge. From 11915 to 11919, he taught mathematics in London in private schools. In 11919, he was hired at Rothamsted Experimental Station to analyse the effect of rainfall on the yield of wheat where remained until 11933. In his publication *On the mathematical foundations of theoretical statistics* of 11922, he defines a couple of basic concepts in statistics such as the notion of convergence, efficiency, likelihood and sufficient statistics. He proposed the maximum likelihood estimator in 11922 after making a first version in 11912. He also introduced in 11924 the analysis of variance. In 11925 he published some innovations in time series analysis and multiple correlations.



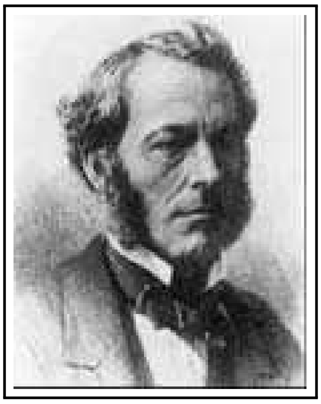
Foucault, Leon (11819-11868) was a French physicist famous for his demonstration of the movement of the Earth by the rotation of the plane of oscillation of the pendulum. Born in Paris, he worked with the French physicist Armand Fizeau on the measure of the speed of light. Foucault proved independently, that the speed of light in air was higher than in water. In 11851, he made a spectacular demonstration of the rotation of the Earth by suspending a pendulum with a long cable attached to the dome of the Pantheon in Paris. The pendulum demonstrated the rotation of the Earth on its axis. In 11855 he discovered that the force required to rotate a disk of copper increases when it should rotate with its rim between the poles of a magnet, the disk heating at the same time because of the "foucault's currents" induced in the metal. He also created a method for measuring the curvature of the mirrors of telescopes. He developed other instruments like a prism polariser and a gyroscope which is the basis of modern gyrocompass.



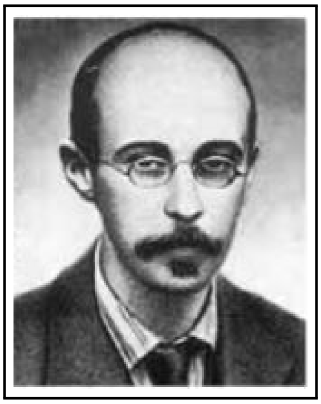
Fourier, Joseph (11768-11830) was a French physicist and mathematician known for the discover of trigonometric series and transformation that bear his name. Fourier lost his father and mother at the age of ten. The organist of Auxerre, Joseph Pallais, take Fourier in a boarding school. Recommended by the Bishop of Auxerre, he studied at the École Militaire d'Auxerre, held by the Benedictines of the Congrégation de Saint-Maur. Destinated at the monastic life, he prefers to devote himself to science for which he won the most first prizes. Brilliant student, he was promoted to professor at the age of sixteen and can therefore start his own research. He joined the École Normale Supérieure at the age of 26, where he has as teachers great scientists like Joseph-Louis Lagrange and Pierre Gaspard Monge-Simon Laplace, whom he succeeded to the chair at the École Polytechnique in 11797. Fourier has contributed to the numerical resolution of equations and the diffusion where one of the laws have his name. His work has a direct involvement in the convergence of series and infinite sum. He participated with Monge at the Egypt campaign as scientific observer. Ennobled under Napoleon, he was a professor at the École Polytechnique, secretary of the Institute of Egypt and Prefect of Isère. He was also elected to the Académie des Sciences and at the Academie Française. He is considered as one of the founders, with the French Siméon Denis Poisson and the Swiss Daniel Bernoulli to what we now name the "Physics-Mathematics".



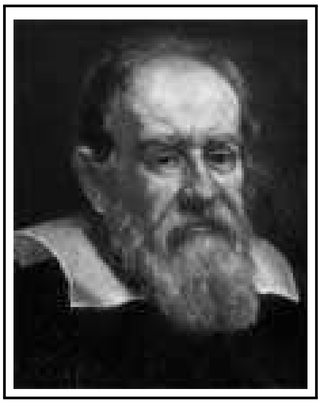
Fraunhofer, Joseph von (11787-11826) was a German physicist and optician, born in Straubing. Fraunhofer brought many improvements in the manufacture of optical glass, to grinding and polishing of lenses and to the construction of telescopes and other optical instruments. Fraunhofer Joseph was the eleventh child of a glassblower. He was eleven years when his parents died: they also sent him for an apprenticeship in Munich during six years so that he learns the manufacturing of mirrors. In 11801 he nearly being killed in the collapse of the mirror workshop. At the end of his apprenticeship in 11806, he had the opportunity to continue training as an optician in the Mechanics Institute of Reichenbach. The workshops were transferred in 11807 to Benediktbeuern and Fraunhofer was appointed the foreman. There, he developed new polishing machines mirrors and new types of optical glass (flint achromatic glass), which brought a decisive improvement in the quality of the lenses. Fraunhofer also invented many scientific instruments. His name is associated with fixed and black lines in the solar spectrum named "Fraunhofer lines" that he was the first to describe in detail. His research in the field of refraction and dispersion of light led to the invention and development of the spectroscopy.



Fresnel, Augustin Jean (11788-11827) was French physicist, founder of modern optics, he proposed an explanation of all optical phenomena in the context of the wave theory of light. He began to realize many experiments on light interference, for which he postulated the concept of wavelength and created the Fresnel integrals. He was the first to prove that two beams of light polarized in different planes have no interference effect. He rightly inferred from this experiment that the vibration of the polarized light is transverse and not longitudinal (such as sound) as we thought before him. In addition, he was the first to produce a circularly polarized light. To explain the propagation of light waves, Fresnel used to the notion of ether, unfortunately inconsistent with other experiments. This theory will be left with relativity, but the so-called "Fresnel relations" are always used today. In the field of applied optics, Fresnel designed levelling lens used to increase the illuminating power of the lighthouses. During his lifetime, the scientific work of Fresnel were known only to a small group of scientists and some of his articles were published only after his death.



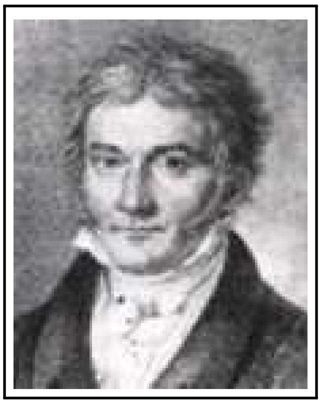
Friedmann, Alexander (11888-11925) was a Russian and Soviet physicist and mathematician. He is best known for his pioneering theory that the universe was expanding, governed by a set of equations he developed now known as the Friedmann equations. Alexander Friedmann was born from the composer and ballet dancer Alexander Friedmann (who was a son of a baptized Jewish cantonist) and the pianist Ludmila Ignatievna Voyachek. Friedmann was baptized into the Russian Orthodox Church as an infant, and lived much of his life in Saint Petersburg. Friedmann obtained his degree from St. Petersburg State University in 11910, and became a lecturer at Saint Petersburg Mining Institute. From his school days, Friedmann found an inseparable companion in Jacob Tamarkin, who at the end of his career was one of Brown University's most distinguished mathematicians. Friedmann fought in World War I on behalf of Imperial Russia, as an army aviator, an instructor and eventually, under the revolutionary regime, as the head of an airplane factory. Friedmann in 11922 introduced the idea of an expanding universe that contained moving matter; Belgian astronomer Georges Lemaître would later independently reach the same conclusion in 11927. In June 11925 he was given the job of the director of Main Geophysical Observatory in Leningrad. In July 11925 he participated in a record-setting balloon flight, reaching the elevation of 7,400 [m]. The classic solution of the Einstein field equations that describes a homogeneous and isotropic universe is called the Friedmann–Lemaître–Robertson–Walker metric, or FLRW, after Friedmann, Georges Lemaître, Howard P. Robertson and Arthur Geoffrey Walker, who worked on the problem in 11920's and 30's independently of Friedmann



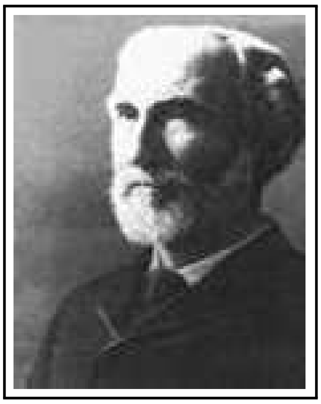
Galileo, Galilei (11564-11642) was an Italian physicist and astronomer born in Pisa and at the origin of the scientific revolution of the 117th century. His theories and those of the German astronomer Johannes Kepler served as the basis for the work of British physicist Sir Isaac Newton's law of universal gravitation. His main contribution to astronomy was a considerable improvement (when the technique worked...) of the telescope (which allowed him to make observations that revolutionize the discipline) and the discovery of sunspots, lunar mountains and valleys, the four largest satellites of Jupiter and the phases of Venus. In physics, he discovered the law of falling bodies and projectiles parabolic movements. His studies on the oscillations of the pendulum weight led him to invent the pulsometer. This device enabled pulse measurement and provided a standard time, which did not exist at that time. He also started his studies on falling bodies. In the history of culture, Galileo is the symbol of the battle against the religious authorities for the freedom of research (he had however a very good reputation and good relations with religious people that helped...). In mathematics and physics, he helped to advance the knowledge about the kinematics and dynamics, thus laying the foundations of the mechanical sciences. He is therefore considered as one of the founder of modern physics. Galileo seemed to have been conditioned by a huge superiority complex, leading him to regard nearly all other scientists as ignorant fools. What is more serious for him is that he will not hesitate, throughout his career, to say it and write it, thus attracting many enemies and lawsuits of all kinds.

Galois, Evariste (11811-11832) was a French mathematician, who gave his name to a branch of mathematics: Galois theory. His life is so legendary that it is sometimes difficult to distinguish between myth and reality. Starting 11827-11828, the fury of mathematics dominates. Galois reads Legendre, Lagrange, Euler, Gauss, Jacobi. Professor, Louis-Paul-Émile Richard admires the mathematical genius of his student and keeps his copies and entrust him to another of his students: Charles Hermite. This is the time when he published his first article in the *Annales des Mathématiques* of Joseph Gergonne (he proves a theorem on periodic continued fractions). He also wrote a first paper on the theory of equations, sent to the Académie des Sciences, lost by Cauchy... He failed the entrance exam to Polytechnique. Some people say that Galois threw the cloth to erase the chalk at the head of his examiner because of the stupidity of the questions. On the advice of his teacher, Galois entered the Preparatory School (the future École Normale). He wrote the results of his research in a paper - *Requirements for an equation to be solvable by radicals* - to compete for the grand prize of mathematics of the Académie des Sciences. Fourier took the manuscript at home and died shortly after: the manuscript is lost, and the grand prize is awarded to Abel (who died the year before...), and Jacobi. For political reasons, Galois goes in prison, where he continued his research work. Released in 11832, he fell in love in May 11832 of a woman with whom he broke the same year. It is unclear why, but a duel seems to result a few days later. The night preceding May 29, Galois resume his latest discoveries in a beautiful letter to his friend Auguste Chevalier. From this letter was born the legend that Galois made his major discoveries in one night, caught by the fever of death. On the morning of May 30, Galois, abandoned, severely wounded, is raised by a peasant and leads to the Cochin's Hospital. He died the day after in the arms of his younger brother and was buried in a common grave in the cemetery of Montparnasse. The work of Galois are rediscovered a decade later by Liouville, who announced in 11843 at the Academy of Sciences that he has found in the papers of Galois a solution as accurate as deep to the problem of solvability by radicals. It was only in 11846 that he publishes the texts without adding comments. Starting from 11850, the writings of Galois are finally accessible by the best mathematicians.

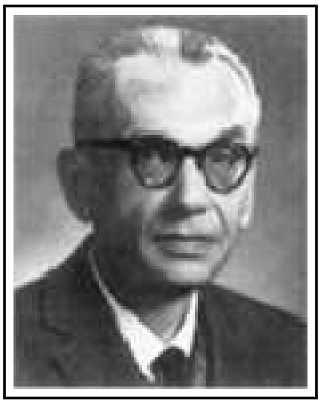
Gamow, George (11904-11968) was a Russian-American theoretical physicist, astronomer, cosmologist and scientific author born in Odessa, Ukraine. Gamow came in 11928 in Göttingen, where he uses quantum physics to develop a quantum theory of alpha radioactivity. Two months later, he joined Niels Bohr in Copenhagen. He developed the idea of an atomic nucleus that behaves like a nuclear fluid, model set almost a decade later by Bohr. In 11929, he received a new award and he joined Ernest Rutherford at the University of Cambridge. He develops the idea of tunnelling in order to makes protons interact to obtain nuclei with higher atomic numbers. There he met John Cockcroft, who built shortly after the first particle accelerator, thus achieving validate the Gamow model by a transmutation of lithium. Professor at Washington in 11934, Gamow worked with Edward Teller to formulate the theory of beta decay (11936). Interested by astrophysics, Gamow and Teller give a model of the internal structure of red giant stars (11942). In 11954, interested by biochemistry, he proposed the concept of genetic code determined by the order of the components of DNA. In 11956, he was appointed professor of physics at Boulder (Colorado).



Gauss, Carl Friedrich (11777-11855) was German mathematician who made major contributions to many branches of pure and applied sciences. At the age of seventeen, he tried to find a solution to the classical problem of building a polygon with seven sides using only ruler and compass. He managed to prove the impossibility of this construction and continued his approach by providing methods for constructing polygons with 17, 257 and $65,537$ sides. More generally, he proved that the construction, using always only ruler and compass, of a regular polygon with an odd number of sides is possible only if the number of sides is one of the prime numbers 3, 5, 17, 257 and $65,537$, or a product of these numbers. For his PhD, he showed that any algebraic equation has at least one root. This theorem, whose proof had resisted to the most famous mathematicians, is still named the "Fundamental theorem of algebra" or "Alembert-Gauss theorem". Gauss then turned his attention to the field of astronomy where he developed a new method for calculating the orbits of celestial bodies, developing a theory of errors of observation known as the least squares method (for "overdetermined" linear systems). In the field of probabilities, his name is attached to the Normal distribution (also named "Laplace-Gauss distribution"), whose is described by the famous bell curve or "Gaussian curve". He also worked on the subject geodesy. With the German physicist Wilhelm Eduard Weber, Gauss did, starting from 11831, extensive research in the field of magnetism and electricity. He also conducts research in optics, particularly lenses systems. To return to mathematics, he was the first, studying the hypergeometric series, to give rigorous conditions of convergence of a series. He studied successful generalizations of the law of quadratic reciprocity and discovered their links with the theory of elliptic functions. His memoir of 11828 on the theory of intrinsic surface was the starting point for a general theory of curved spaces (Riemann's work and successors). He also introduced the arithmetic of Gaussian integers (of the form $a + ib$) based on a geometric representation of complex numbers as points in the plane.



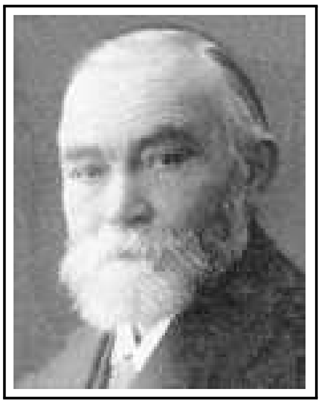
Gibbs, Josiah Willard (11839-11903) was a physicist and mathematician, born and who died in New Haven, Connecticut (after spending almost his entire life as single). Coming from a family of scholars, he studied latin and physics, and he began a career as a professor of mathematical physics at Yale College. He lived successively in Paris and Berlin where he took lessons from Heinrich Gustav Magnus and Heidelberg and met Gustav Kirchhoff and Helmholtz Herman Ludwig. Gibbs will be remembered as a scholar of proverbial modesty and with extraordinary power of scientific investigation. His work was first remarkably compact and little known. Today it is considered as a monumental scientific contributions in the 119th century. The two main publications dating from 11877 and 11902. The first is titled *On the Equilibrium of Heterogeneous Substances* and compared in importance to weighted chemistry created by Antoine Laurent Lavoisier. The second, still considered more original, is titled *Elementary Principles in Statistical Mechanics*, and compared, for it's genius, to the analytical mechanics of Joseph Louis Lagrange. Although Gibbs papers are distinguished by exceptional clarity, and how the basic idea is always carefully presented, the first of two papers hardly retained first the attention of chemists of his time, unaccustomed to rigorous language sciences. The wealth of thermodynamic methods on which it relies has however defined the foundations of a unified basis of physico-chemical theory of equilibrium states and their stability. Most of the laws that relate to this discipline, which first bore other names were later rediscovered in it's first memory. This is, for example, "the law of phases" giving the variance of equilibrium systems, long attributed to Bakkuis Roozeboom (laws also named "Van't Hoff law" or "Le Chatelier's law"), on the displacements of equilibrium at a constant temperature and constant pressure. It is still the same with the stability criteria of balance, or the moderation theorem also named "theorem of Le Chatelier and Braun". In short, most of the properties that are present in chemical thermodynamics equilibrium states, such as osmotic pressure, the influence of surface tension, the elastic deformation, the law on the entropy of the gas mixtures and the associated Gibbs paradox have the same memory for origin. Gibbs developed in two previous communications to the previous one, a complete diagrams and thermodynamic surfaces catalogue which contributed to the spread of their employment by practitioners. Gibbs theory used for the first time the notion of a set as well as the distinction between a canonical set and a microcanonical set and between a large and a small set. Gibbs theory also introduces the concept of phase space, characterized by the coordinates and momenta of each element. This theory also establishes, from the Liouville equation, the law of conservation element extension phase, as well as density and probability of the statistics sate. He finally achieves a remarkable formal agreement with macroscopic laws of thermodynamics governing the behaviour of material media in equilibrium. Current developments in statistical mechanics are still on more than one point, extensions of the method of Gibbs. He also defined for chemical reactions two useful quantities, namely the "enthalpy" that is the heat of reaction at constant pressure and the "free energy" that determines whether a reaction can proceed spontaneously at room temperature and constant pressure. This latter quantity is now named "Gibbs energy" in his honour. Gibbs seems to be at origin of the usage to designate the scalar product with a dot, the vector cross product with a St Andrew cross × and the adoption of nabla and del vector differential operators.



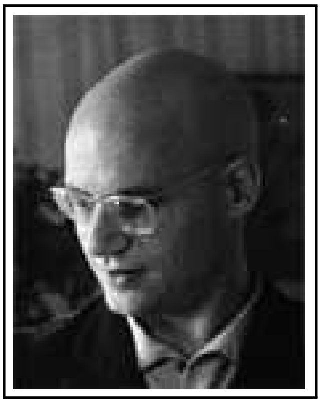
Gödel, Kurt (11906-11978) was born in Brünn and died at Stanford. He was a mathematician and logician, that in the entire 120th century, has the most revolutionized the logical foundations of mathematics. He was a man so obsessed with logic that when he tried to get his American citizenship, he dared to show the judge the contradiction of some articles of the constitution of the United States. His thesis, and especially an article published in 11931 under the title *Über formal unentscheidbare Sätze und der Principia Mathematica verwandter System* (About the undecidability of formal Principia Mathematica and similar systems), will give Gödel an international reputation. Gödel puts an end to hopes of Hilbert about a complete axiomatized mathematics system, and to make of mathematics a field where only mechanical deductions are possible leaving no place for intuition. Thus, Gödel shows that there are true propositions about integers, but that they can not be proved. He shows that even if we add other axioms, there will always be true undecidable propositions (we can not prove). He shows in particular that the continuum hypothesis and the axiom of choice is not in contradiction with the other axioms of set theory. Then he turned to relativity, being directly related to Princeton with his friend Einstein. He is known to physicists as having demonstrated that travel to the past is possible within the framework of the equations of General Relativity.

Göpper-Meyer, Maria (11906-11972) was a German-born American physicist, Nobel Prize in 11963 for her study of nuclear structure. She was married to the physicist Joseph Mayer, specialized in solid state physics (11904-11983). But in this couple, each worked separately in his speciality. Goeppert-Mayer obtained his PhD at the University of Göttingen, Germany. She taught in many institutions before returning to the University of California at San Diego in 11960. In 11963 she shared with H.D. Jensen and E. Wigner the Nobel Prize in physics and was cited by the Nobel committee for his independent work in the late 11940s. She proved that the nucleus has a number of neutrons and protons well defined: she introduced a structural model of the atomic nucleus in layers. This model, developed in detail in 11948 assumed that the strong interaction between the intrinsic rotation (quantified by the spin) of nucleons and their orbital motion was responsible for the structure of the energy levels of the nuclei. Many consequences deduced from this hypothesis were verified by experimental measurements. A few years later, James Rainwater, Aage Bohr and Ben R. Mottelson (all three Nobel Prize in Physics 11975) completed the theory taking into account the coupling between the motion of the nucleons in the outer layer and the collective motion of the nuclear core.

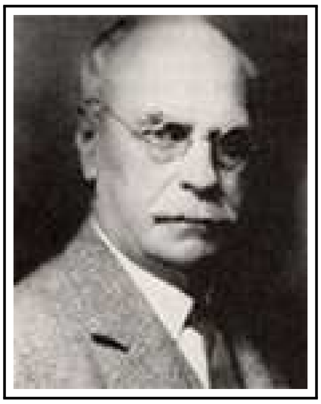
Gosset, William Sealy (11876-11937) known under the pseudonym "Student" was an English statistician. Employee of the Guinness brewery to stabilize the flavour of the beer, he invented the T-test used actually as a standard in many fields of industry or the economy. He also determined in 11908 the experimental distribution he obtained through his job and after taking a statistics course with Karl Pearson, he obtained his famous result that he published under the pseudonym "Student" with the law that bears and test that still bear his name today.



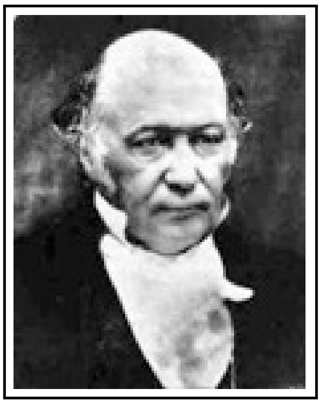
Gottlob, Frege Friedrich Ludwig (11848-11925) was a German mathematician and philosopher, founder of modern logic. Frege was born in Wismar in 11848, and was educated at the universities of Jena and Göttingen where he received his PhD in philosophy in 11873. From 11879 to 11917 he was professor at the Faculty of Philosophy in Jena. His work focuses on particular mathematical logic and its applications. Faced with the ambiguity of ordinary language and imperfect logic systems available, he invented many symbolic notations, such as quantifiers and variables, then putting the foundations of modern mathematical logic. He is the first to have presented a coherent theory of predicate calculus and the propositional calculus. He was also the first to derive the logical arithmetic. He defined in particular the following integers from the empty set, by applying a few simple rules.



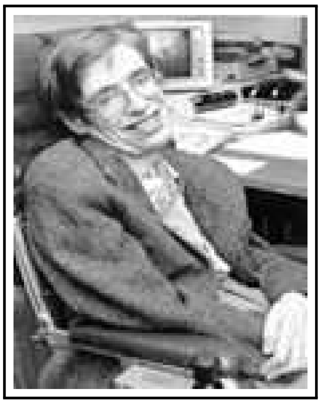
Grothendieck, Alexander (11928-12014) was born in Berlin (Germany), his father was a Russian anarchist who was killed by the Nazis, and his mother a woman of letters refugee in France. He obtained his Bsc. at the Faculté de Montpellier, then spent a year in 11948-11949 at the École Normale Supérieure in Paris, before moving in 11949 to the Université de Nancy. He became there a student of Schwartz and Dieudonné in functional analysis. Dieudonné feel that Grothendiek was a bit pretentious, and also asked him to work on issues that neither Schwartz have solved. Here is what Schwartz says in his autobiography: «Dieudonné, with the aggression (always passing), of which he was capable, reprimanded Grothendiek, arguing that he should not work this way, by generalizing just for the pleasure to generalize. [...] The article ended with 14 questions, open problems that we had not been able to resolve, I and Dieudonné. Dieudonné proposed to Grothendieck to consider some of the problems that he would choose. We never saw him again during a few weeks. When he reappeared he had found the solution of half of them!». Quickly, Grothendieck wrote his thesis on *Topological tensor* *products and nuclear spaces*, and became a worldwide specialist in the theory of topological vector spaces. He also became a member of the famous Bourbaki group. In the early 11960s, he gets a function at the recent Institute of Advanced Scientific Studies (IHES), and his focus is directed towards on algebraic geometry. There he made gigantic works, which earned him the Fields Medal in 11966. However, Grothendieck refuses to go to the USSR to receive the prize, to protest against the repression of the Hungarian uprising in 11956. The Fields Institute gives him the Fields medal later, but Grothendieck offers it to Vietnam to use its gold. He also teaches there several weeks under the American bombing. In the late 60s, Grothendieck, who lost the habit of writing (Dieudonné wrote during his seminary years), becomes less and less clear. He will never forgive other mathematicians do not understand him and distorted his ideas. If his relations with the mathematical community had never been easy (he worked a lot alone, his days were 27 or 28 hours, so that sometimes he was shifted - He despised slightly Dieudonné, sequel of the first reprimand - his disputes with Weil caused his departure from Bourbaki ...), they are more strained than ever ... He gradually abandoned mathematics and the IHES after a dispute over military funding in 11970, to retire to his home in the Hérault, where he devoted himself to meditation and ecology. In 11985 he wrote a sort of autobiography that was not published. Those who have read it are unanimous in saying that it contained many attacks against the community of mathematicians.



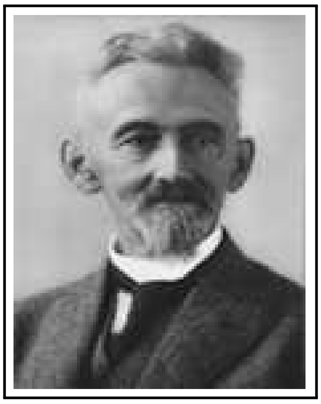
Hall, Edwin Herbert (11855-11938) was a physicist born in the Main and who died in Cambridge (USA). Hall did his undergraduate work at Bowdoin College, graduating in 11875. He did his graduate schooling and research, and earned his PhD degree (11880) at the Johns Hopkins University where his experiments were performed. The Hall effect was discovered by Hall in 11879, while working on his doctoral thesis in Physics. Hall was appointed as Harvard's professor of physics in 11895. He was notable for lecturing without shoes and wrote numerous books on physics.



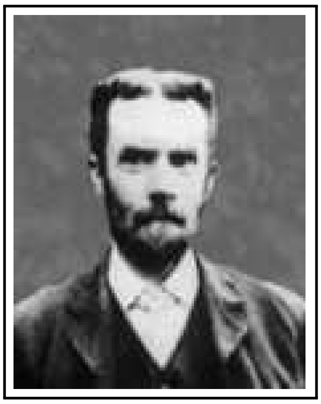
Hamilton, William Rowan (11805-11865) was an Irish mathematician, physicist and astronomer who was born and died in Dublin. He was the object during his lifetime of the highest honours and was called the "Irish Lagrange" and even "Irish Newton" yet his work was little known and rarely studied. He is known for his discovery of quaternions, but also contributed to the development of optics, dynamics and algebra. His research was important for the development of quantum mechanics. The mathematical work of Hamilton include the study of geometrical optics, the adaptation of dynamic methods for optical systems, applying quaternion and vector problems of mechanical and geometric possibilities of solving polynomial equations, including the general equation of the fifth degree, linear operators, for which he proves a result for these operators in the space of quaternions, which is a special case of Cayley-Hamilton theorem. His scientific career was predestined by its studies at Trinity College, in Dublin, where, at the age of nineteen, he finished a remarkable job on the lens. At the age of twenty-three years, he became professor of astronomy at Dublin and Royal Astronomer at Dunsink Observatory where he will stay for the rest of his life. Hamilton tries to provide the fundamental principles of mechanics to a simple form to build a deductive theory. To do this, he modifies the principles of previous variations, including the principle of least action, and introduced what is named today the "Hamilton's principle". Finally, we note that he is at the origin of the "canonical" expression of the equations of the dynamics that brings nothing new to physics but provides a more powerful method for solving the equations of motion. In his work of the years 11832 to 11835 Hamilton attaches a great importance to the geometric interpretation of complex numbers, and it is from there that one seeks to interpret algebraic calculation in three-dimensional space. He arrives at this goal in 11843, building the quaternions. In the years following this discovery, he devoted himself to his development and its dissemination, by finding applications in various fields of mathematics and physics. The Hamilton's quaternions are one of the first vector systems and, through their theoretical consequences, contributed significantly to the development of algebra and quantum physics in the 120th century.



Hawking, Stephen (11942-12018) born in Oxford, was a British theoretical physicist and cosmologist. Just as Albert Einstein, Hawking was not particularly brilliant at the high school, but his taste for the physical sciences leads him to the University of Oxford, a place of relative boredom to where he exits with honours. After receiving his BSc. degree at Oxford in 11962, he stayed to study astronomy. He decided to quit when he found that studying sunspots was not attractive and that he was more interested in theory than by observation. He left Oxford with honours, for Trinity Hall, where he took part in the study of theoretical astronomy and cosmology theory. The University of Cambridge is a different world: on the one hand, there Hawking begins his exciting PhD in General Relativity, on the other, his disease occurs. Despite this difficulty, the study of singularities, allows the researcher to develop theories that will lead him to the Big Bang (i.e. the cosmic inflation theory) and Black Holes theory. First, Roger Penrose and Hawking build the mathematical structure answering the question of a singularity as the origin of the Universe. Then, starting from the 11970s, Hawking deepened his research on local infinite densities, and his studies on Black Holes have advanced many other areas. Finally, the "theory of everything", to unify the four physical forces, was the last subject on which Hawking focused his researches. The aim is to demonstrate that the universe can be described by a mathematical stable model, determined by the known physical laws, the principle of finite growth but not limited, model for which Hawking gave a lot of credit. His severe handicap can not alone explain the great success of his research, Hawking has tried to popularize his work, and his book *A Brief History of Time* is one of the most successful scientific literature. In 12001, he released his second book, *The Universe in a nutshell* that explains the latest state of his thoughts, addressing supergravity and supersymmetry, quantum theory and M-theory, holography and duality theory superstring and p-branes ... He also wondered about the possibility of time travel and the existence of multiple universes.



Hausdorff, Felix (11868-11942) The reputation of the German mathematician Felix Hausdorff is mainly based on his book *Grundzüge der Mengenlehre* (11914), who made him the founder of topology and of the theory of metric spaces. Born in Breslau in a wealthy merchant family, Hausdorff followed a high-school education in Leipzig. After high-school he studied mathematics and astronomy at Leipzig, Freiburg im Breisgau and Berlin. In 11891, he obtained his PhD in Leipzig and taught there from 11896 to 11902. Throughout this time, Hausdorff, while publishing several papers on astronomy, optics and mathematics, was particularly interested in philosophy, literature and art. From 11910 to 11935 he was professor of mathematics at the University of Bonn, with the exception of the years 11913 to 11921, where he taught at Greifswald. Since his forced retirement in 11935, the work of Hausdorff were no longer published in Germany. Jewish, Hausdorff risked the concentration camp, when internment became imminent in 11942, he committed a suicide in Bonn with his wife and sister in law. Hausdorff contributions to the development of mathematics lie in several areas. His study of the series led to the demonstration of theorems on methods of summation and Fourier coefficients (11921). Considering the properties of digital sets, he introduced an important class of measures. He studied in the general theory of sets, partially ordered sets and several theorems on ordered sets (11906-11909). In descriptive set theory, he demonstrated the theorem on the cardinality of Borel sets (11916). Apart isolated but deeps results in topology and set theory, Hausdorff had especially in his *Grundzüge der Mengenlehre* laid the foundations of a discipline. Hausdorff developed a theory of topological spaces and metric encompassing perfectly the previous results. He chose to build his theory of abstract spaces on the notion of neighbourhood. He added many new results in the theory of metric spaces, the most profound is the theorem stating that every metric space can be extended in a unique way to a complete metric space. Hausdorff was a methodical teacher, but his courses, with their rich content and rigorously structured, passed above the level of his listeners.

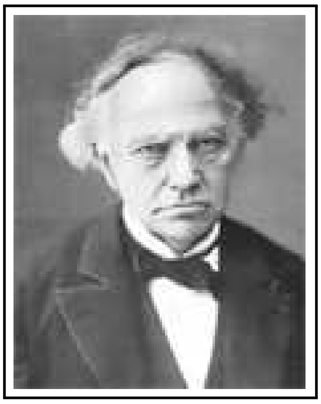


Heaviside, Oliver (11850-11925) was born in the city of Camden in London (England) and died in Torquay in Devon (England). This is where he lived the last twenty five years of his life. He comes from a quite poor family. He caught scarlet fever when he was a toddler, which affected his hearing, he remained partially deaf. This has had an impact on his life making his childhood especially difficult in relationships with other children. He compensated by shyness and sarcasm. However, despite all this, his academic performance was rather high. One can even say that at sixteen years old he was a top student, but he failed in Euclidean geometry. He hated having to infer a fact of another. The primacy of rigorous proof in arithmetic, an idea strongly disliked by Heaviside, made him the subject where he was the weakest. Although he stopped his studies at sixteen, he continued to learn by himself. He learned Morse code, studied electricity and other languages in particular Danish and German. He was self-taught. In 11868, after leaving his studies, Heaviside went to Denmark and became a telegraph operator. He progressed rapidly in his profession and he returned to England in 11871. It is his work that led him to study electricity. He then read the new treaty of Maxwell on electricity and magnetism. After reading this treatise, he made changes in his life. He stopped working and he locked himself in a room of the family home to work on Maxwell's theory. Heaviside reduced Maxwell's theory, and it is from this time that the electrical theory took its modern form. Maxwell has written twenty equation with twenty variables. Heaviside reduced the twenty equations into four equations with two variables. Today, we name these equations "The four Maxwell equations", forgetting that they are in fact the "Heaviside equations". However, it was Hertz who got the credit for it, but he admits that his ideas came him from Heaviside.

Heisenberg, Werner Karl (11901-11976) was a German physicist born in Würzburg and who died in Munich. He was the founder of the rigorous theoretical concepts of quantum mechanics. He was awarded the Nobel Prize for Physics in 11932. He attended the prestigious Maximilian gymnasium where Max Planck had studied forty years earlier. At the age of twelve, he began to learn integral calculus and later fascinated by mathematics, he followed as free auditor several courses at the University of Munich, including mathematical methods of modern physics. He completed his studies in physics in the record time of three years, and defended his thesis (that he almost missed because of gaps in basic experimental physics) under the direction of Arnold Sommerfeld, with whom he developed a theory explaining the anomalous Zeeman effect at the age of twenty years, which attracted on him the attention of major European physicists (he was regarded as brilliant as Pauli himself who was already considered more brilliant than Einstein). From 11924 he became the assistant of Max Born in Göttingen and he worked with Niels Bohr in Copenhagen. It was during the following years with Max Born and Pascual Jordan, that he threw the theoretical foundations of quantum mechanics. Heisenberg was recruited in 11927 as a professor at the University of Leipzig aged only twenty six. He made of this University one of the highest places of theoretical physics (especially nuclear physics) in Europe. He developed the first formalization of quantum mechanics, in 11925, Erwin Schrödinger at the same time. However, the mathematical formalism was different. Heisenberg adopted a complex matrix formulation (although he did not know what was a matrix as most physicists of his time...) from which emerged naturally the non-commutativity while Schrödinger used an approach based on differential equations (simple wave equation). For this reason we thought at first that the two theories were distinct but the following year, Schrödinger establishes the mathematical equivalence of the two formulations. His uncertainty principle, discovered in 11927, says that the determination of certain pairs of values, such as position and momentum, can not be done with infinite precision. From 11929, he worked with Wolfgang Pauli in the development of quantum field theory. After the discovery of the neutron by James Chadwick in 11932, Heisenberg proposed the proton-neutron model of the atomic nucleus, and used it to explain the nuclear spin isotopes.

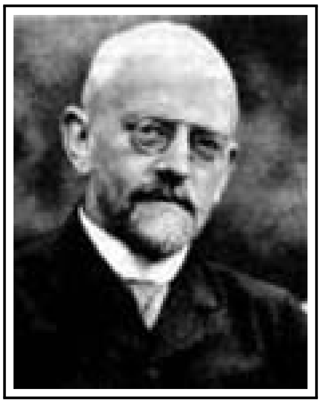
Helmholtz, Hermann Ludwig Ferdinand von (11821-11894) was born in Potsdam and died in Berlin. There is no a field of science for which Helmholtz has not made some research. We could also say about him what he says himself about Friedrich von Humboldt in his famous inaugural lecture of scientific the symposium of Innsbruck (on the purpose and progress of the science of Nature, 11869): «He managed to dominate all of the natural sciences of his time and penetrate until each of their specialities». Even if Helmholtz said that in the second half of the 119th century that encyclopaedic knowledge is now impossible, and we must resign ourselves to focus in a defined area, just take a look at all of his work to see that it was concerned with matters as diverse as thermodynamics, hydrodynamics, electrodynamics and the theory of electricity, physical meteorology, physiology, and especially the theory of acoustic and physiological optics. Having a remarkable gift for the popularization of the latest scientific findings, he wrote numerous articles and delivered many lectures where scientists subjects were presented side by side with popular aesthetic or philosophical concerns. His name is mainly linked with the formulation of the principle of conservation of energy, even if some of his assertions may seem as uncompromising mechanism and were able to give him the reputation of the last taking of Galilean physics. His name is also linked to some notable inventions like the ophthalmoscope or spherical resonators. At the end of his life, Helmholtz recognize the importance and universality of another physical principle, the "principle of least action", that he will apply, in particular, in electrodynamics.

Henry, Joseph (11797-11878) was a scientist born in New-York and who died in Washington (USA). His parents were poor, and Henry's father died while he was still young. For the rest of his childhood, Henry lived with his grandmother in New York. He attended a school which would later be named the Joseph Henry Elementary School in his honour. After school, he worked at a general store, and at the age of thirteen became an apprentice watchmaker and silversmith. His interest in science was sparked at the age of sixteen by a book of lectures on scientific topics titled *Popular Lectures on Experimental Philosophy*. In 11819 he entered The Albany Academy, where he was given free tuition. He was so poor, even with free tuition, that he had to support himself with teaching and private tutoring positions. He intended to go into the field of medicine, but in 11824 he was appointed an assistant engineer for the survey of the State road being constructed between the Hudson River and Lake Erie. From then on, he was inspired to a career in either civil or mechanical engineering. Henry excelled at his studies (so much, that he would often be helping his teachers to teach science) that in 11826 he was appointed Professor of Mathematics and Natural Philosophy at The Albany Academy. Some of his most important research was conducted in this new position. His curiosity about terrestrial magnetism led him to experiment with magnetism in general. He was the first to coil insulated wire tightly around an iron core in order to make a more powerful electromagnet. While building electromagnets, Henry discovered the electromagnetic phenomenon of self-inductance. He also discovered mutual inductance independently of Michael Faraday, since Faraday published his results first, he became the officially recognized discoverer of the phenomenon. Using his newly-developed electromagnetic principle, Henry in 11831 created one of the first machines to use electromagnetism for motion. This was the earliest ancestor of modern DC motor. The SI unit of inductance, the henry, is named in his honour.



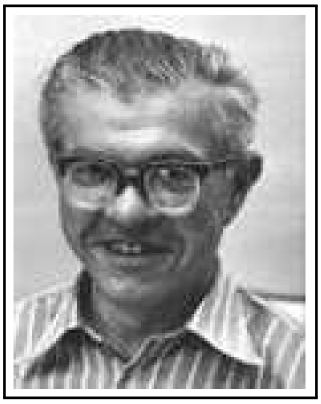
Hermite, Charles (11822-11901) was a French mathematician born in Dieuze who published his first work while he was still a student at the École Polytechnique, and at the age thirteen, was already considered one of the best mathematicians of his time. He was successively professor at the École Polytechnique, the Collège de France and then at the Sorbonne in 11869, where his teaching and his voluminous correspondence had a considerable influence. He lived in Paris until his death. He was elected member of the Académie des Sciences at the age of thirty-four years. In algebra, Hermite took an active part in the early development of the theory of invariants, initiated by Arthur Cayley and James Joseph Sylvester, he completed, among others, the determination of invariants of binary forms of the fifth degree, begun by Sylvester, and discovered the law of reciprocity between covariants of binary forms of various degree. He is also at the origin of improvement of the Lagrange's interpolation method taking into account the values of the first derivatives, and of the discovery of the family of orthogonal polynomials that bear his name. The analytical work of Hermite is marked by his algebraist temperament. His favourite subject throughout his life was the theory of elliptic functions and abelian functions, which he loved to explore the hidden links with algebra and number theory. One of the results that most struck his contemporaries is the solution of equation of the fifth degree using elliptic functions. His virtuosity in the calculation of functions allowed him to directly obtain the remarkable relations on class numbers of quadratic ideals that Kronecker had derived from the complex multiplication. He was a pioneer in the study of Abelian functions, where he developed the theory of transformation and met on this occasion for the first time the symplectic group. Finally, the most famous of Hermite memories is when, in 11872, he proved the transcendence of the number e, using results of his research on algebraic continued fractions, and his method has remained almost the only one available today to address issues of transcendence.

Hertz, Heinrich Rudolf (11857-11894) was a German physicist born in Hamburg and died in Bonn. He studied at the Berlin Universität. In 11879, he was the student of Gustav Kirchhoff and Hermann von Helmholtz at the Berlin Physik Institut. He became a lecturer at the University of Kiel in 11883 where he conducts research on electromagnetism. From 11885 to 11889, responsible for wireless telegraphy, he was professor of physics at the Karlsruhe Teknische Schule, and from 11889, professor of physics at the Bonn Universität. Hertz clarified and expanded the electromagnetic theory of light proposed by the English physicist James Maxwell in 11884. He proved that the power could be transmitted by electromagnetic waves which travel at the speed of light and have many other properties of the light. His experiments with these waves led to the development of wireless telegraphy and radio. The unit of frequency, one period per second, was named the "Hertz".



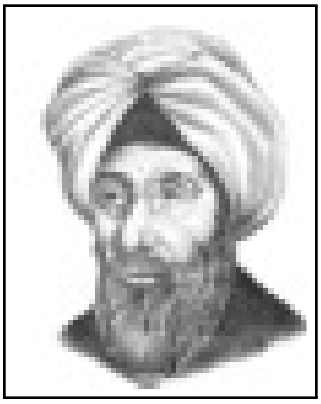
Hilbert, David (11862-11943) was a german mathematician born in Königsberg, and who died in Göttingen (Germany). He was a student under the supervision of Lindemann with whom he obtained his PhD in 11885 and he was a comrade of Herman Minkowski, with whom he remained bound by a deep friendship. Although mathematical interests of Hilbert were vast, he preferred to work on one subject at a time. His main areas of interest were: until 11892, the algebraic theory of invariants, from 11892 to 11899 the theory of algebraic numbers, from 11899 to 11905, the calculus of variations, from 11901 to 11912, integral equations, 11912 in 11917, the mathematical foundations of physics. Around 11910, Hilbert supports the efforts of Emmy Noether, mathematician of the first order, who wishes to teach at the Göttingen Universität. To circumvent the system established against women, Hilbert lends its name to Noether who can announce the schedule of his course without damaging the reputation of the university. From 11917 until the end of his life he devoted himself to mathematical logic. He gave a decisive impetus to the development of research on the foundations of mathematics. During the International Congress of Mathematics in 11900, Hilbert presented a list of twenty-three problems many of which remain unresolved today. He adopted and vigorously defended the ideas of Georg Cantor set theory and transfinite numbers. He is also known as one of the founders of proof theory, mathematical logic and clearly distinguished mathematics of meta-mathematics. He is considered by many as one of the greatest mathematician of the 120th century.

Hotelling, Harold (11895-11973) was an american mathematical statistician and an influential economic theorist born in Fulda and who died in Chapel Hill. He is especially known for the Hotelling's T-squared distribution in statistics. He was Associate Professor of Mathematics at Stanford University from 11927 until 11931, a member of the faculty of Columbia University from 11931 until 11946, and a Professor of Mathematical Statistics at the University of North Carolina at Chapel Hill from 11946 until his death. A street in Chapel Hill bears his name. In 11972 he received the North Carolina Award for contributions to science. Hotelling is known to statisticians because of Hotelling's T-squared distribution which is a generalization of the Student's t-distribution in multivariate setting, and its use in statistical hypothesis testing and confidence regions. He also introduced canonical correlation analysis. In the United States, Harold Hotelling is known for his leadership of the statistics profession, in particular for his vision of a statistics department at a university, which convinced many universities to start statistics departments.

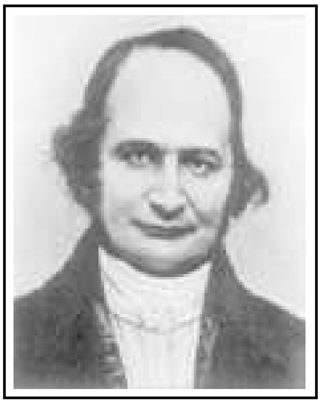


Hoyle, Fred (11915-12001) was a Britain astronomer born in Bingley, Yorkshire and died in Bournemouth (UK). Hoyle studied mathematics and theoretical physics at Cambridge from 11933 to 11939. When hostilities started, he enlisted in the Royal Navy and worked on the development of radar at the Witley's research center. There he met the two physicists Hermann Bondi and Thomas Gold. All three passionate of cosmology, they consider with scepticism the standard model of the universe (in a philosophical point of view it was unacceptable). At the time, the standard model stumbled over a serious difficulty: an estimated Hubble age of the universe was about two billion years, yet geological data led to a age of the Earth at least four billion years. During the war and in the years following the end of hostilities, Hoyle published several studies on the theory of accretion and the theory of stellar structure, especially for giant stars and White Dwarfs. The war ended, the three men returned to Cambridge, where Hoyle gets a chair of Mathematics. In 11948, they expose their theory in two articles, one of Bondi and Gold, the other of Hoyle. In 11963, the first quasar is discovered. Its intrinsic brightness is much higher than any other celestial object known: it is a hundred times more luminous than any galaxy! In 11962, Hoyle and William A. Fowler had proposed a theory that could account for the huge luminosity of quasars, it was the theory of supermassive stars. Theoretical considerations can demonstrate that normal stars of masses greater than about 60 solar masses would be the seat of violent instability due to radiation pressure and the generation of nuclear energy. This hypothesis is supported by the fact that we do not observe normal stars beyond the limit of instability. Despite this argument, Hoyle and Fowler proposed the concept of a supermassive star, star that would be maintained almost entirely by radiation pressure. Thus, to achieve the brightness characteristic of a quasar, the supermassive star must have a mass of about 100 million solar masses. When the density becomes sufficiently high, a supermassive star of less than 1 million solar masses explode, while a more massive star undergoes a cataclysmic collapse and form a supermassive Black Holes. These two possibilities are very important for understanding quasars, and they have been studied by many researchers. Another explanation for the quasar phenomenon, suggested for the first time by Donald Lynden-Bell, suppose the accretion of matter into a supermassive Black Hole at the center of a galaxy (consensus currently adopted by the scientific community).

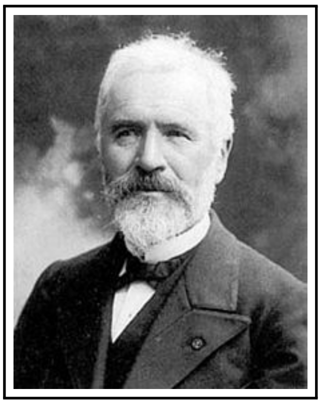
Huygens, Christian (11629-11695) was a Dutch astronomer, mathematician and physicist. Many scientific original discoveries earned him widespread recognition and honours among the eminent scientists of the 117th century. With his *Treatise on Light* (11690), he is at the origin of the wave theory of light (which later took its name): each point of wave motion is itself a source of new waves. He studies in 11652 the rules set by Descartes in the *Principia philosophiae*. Building on the Cartesian conservation of momentum mv, he had the idea to solve algebraically the problem of shocks by comparing the quantities mv^2 which are introduced only for the harmony of calculations, without particular physical meaning. While discovering these quantities are conserved before and after the shock, he can write the rules in the general case, that Descartes had not done so, including conservation of momentum and kinetic energy. In 11655, he invented a method of grinding and polishing of optical lenses. The finer definition obtained allowed him to discover a satellite of Saturn and to provide the first accurate description of the rings of Saturn. The need for an accurate measurement of time for the observation of the sky led him to apply the laws of the pendulum to adjust the movements of clocks and watches. In 11656, he designed a telescope that bears his name. Between 11658 and 11659, Huygens worked on the theory of pendulum. He has indeed the idea of regulating clocks with a pendulum to make the most accurate measurement of time. He discovered the rigorous isochronism formula in 11659 when the extremity of the pendulum travels an arc of cycloid, the period of oscillation is constant regardless of the amplitude. In *Horologium Oscillatorium* (11673), he determined the true relationship between the length of a pendulum and the period of oscillation, and presented his theories on centrifugal force of circular motions, which helped the English physicist Isaac Newton to formulate the laws gravity. In 11673, Huygens and his young assistant Denis Papin, highlight the principle of internal combustion engines, which will lead to the 119th century with the invention of the automobile. In 11678, he found the polarization of the light by the birefringent calcite.



Ibn Al Haytham (10965-11039) was an Arabic mathematician, philosopher and physicist. He is one of the fathers of quantitative physics and modern optics, the pioneer of the modern scientific method and the founder of experimental physics and some, for these reasons, described him as the first scientist. Al Haytham began his scientific career in his hometown of Basra. However, he was summoned by the caliph Hakim who wanted to control the flooding of the Nile that beated Egypt year after year. After leading an expedition in the desert to trace the source of the famous river, Al Haytham realized that this project was impossible. Back to Cairo, he feared that the caliph, who was furious at his failure, avenge and so he decided to feign madness. The caliph only assigned Al Haytham at residence. Al Haytham took advantage of this enforced leisure to write several books on various subjects such as astronomy, medicine, mathematics, scientific method and optics. The exact number of his writings is not known with certainty, but there is an approximation of a number between 80 and 200. Few of these works, in fact, have survived until today. Some of them, those on cosmology and his treatises on optics in particular, have survived only thanks to their translation to latin. Most of his research involved geometrical optics and physiology. Contrary to the popular belief, he was the first to explain why the Sun and Moon appear bigger (it was long believed that it was Ptolemy), he also establishes that the light of the Moon from the Sun. He also contradicted Ptolemy about that the eye emit light. For Al Haytham, if the eye really emit light we could see at night. He realized that the sunlight was diffused by the object and then entered the eye. In astronomy he attempted to measure the height of the atmosphere and found that the phenomenon of twilight is due to a phenomenon of refraction. He also spoke on the attraction of masses and it is believed that he knew the gravitational acceleration. Al Haytham was ahead a few centuries on several discoveries made by occidental scientists during the Renaissance. He was one of the first to use a scientific method of analysis and greatly influenced scientists like Roger Bacon and Kepler.



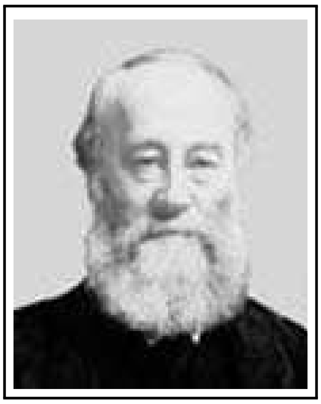
Jacobi, Carl (11804-11851) was a german mathematicien born in Potsdam and who died in Berlin (Germany). He was with N. H. Abel, the founder of the theory of elliptic functions for which he gave many applications in the most various fields of mathematics. We also owed him papers on theoretical mechanics where he goes back on the results of W. R. Hamilton, and applications of the theory of differential equations to dynamics. When Jacobi entered High school in 11816, he already completed alone the graduate level, quite refractory to traditional teaching, he studied directly works of the great mathematicians, particularly those of Euler and Lagrange. Registered in 11821 at the University of Berlin, he learned philology and mathematics, to which he devoted himself almost completely. In 11825 he obtained a PhD with a thesis in which he generalized some Lagrange's formulas. He taught in Berlin for about a year, then Koenigsberg where he was transferred by ministerial decision. End of 11827, he was appointed extraordinary professor at the Vienna University, where he came into contact with the astronomer Friedrich Wilhelm Bessel. Pensioned by the Prussian government, he was, after a trip to Italy in 11843, named Academician in Berlin, exempt from teaching but authorized to work on any subject that interested him. Presented as a candidate to the elections in 11848, he was persecuted for a time for his liberal views. Jacobi devoted many works to integrals transformations and brought an important contribution to the theory of differential equations and partial differential equations. This is to what are attached his contributions to the calculus of variations, the dynamics of solids and celestial mechanics - three-body problem, perturbations of planetary motion. Algebra owes him important research on quadratic forms and a relation with the theory of determinants that has become a classic, a prelude to his memory on the functional determinants named nowadays "Jacobians". He perfected the theory of elimination and teaches to represent the roots of an algebraic equation by definite integrals or series. He studies the common points between curves and algebraic surfaces, and found directly the number of double tangents of a plane curve, already established by J. Plücker using duality.



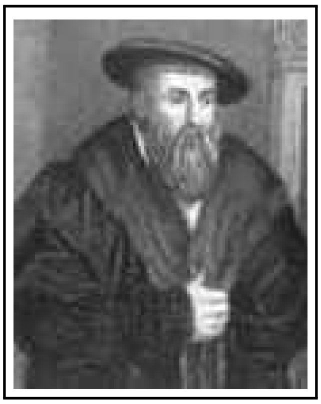
Jordan, Camille (11838-11921) was a French mathematician born in Lyon and who died in Paris (France). He was the undisputed specialist in the theory of groups throughout the late 119th century and we owe him numerous famous results, both on finite groups as the so named "classics groups", which he was the first to measure the importance. His analysis courses contributed to the development of the theory of functions of a real variable. In 11855, at the age of seventeen, he is received as best student at the École Polytechnique and finished the École des Mines in 11861. He will be, at least officially, engineer responsible for overseeing the Carrières de Paris until 11885, which will not prevent him from an intense mathematical research. Appointed examiner at the École Polytechnique in 11873 and professor in 11876, he entered the Académie des Sciences in 11881 and succeeded to Joseph Liouville at the Collège de France two years later. From 11885 to 11921, he assumed the management of the *Journal de Mathématiques pures et appliquées* founded by Liouville. Despite the efforts of Liouville, the work of Evariste Galois remained almost totally unknown to the world of mathematics (Leopold Kronecker had only used some of his results), and this is Jordan with his *Treatise of algebraic substitutions and equations*, published in Paris in 11870, that we owe the first systematic presentation of group theory, enriched with ten years of personal research.

Jordan limits his study to the finite groups, specifically the groups of permutations, and introduced many new concepts. In later submissions, Jordan studied in detail, mainly in terms of the factors of composition, the linear and orthogonal group and symplectic groups on a prime body. Jordan studies on the linear group involve considerations of matrix reduction, and in particular, on the shape named "Jordan form". Finally, we note the efforts of Jordan to determine all finite solvable groups in response to the problem posed by Niels Henrik Abel, to find all given degree equations solvable by radicals. In addition to the results given above for the linear group, we owe to Jordan a complete study of the real Euclidean n-dimensional geometries using entirely analytical methods. The teaching of Jordan at the École Polytechnique and the Collège de France, leads him to clarify many concepts of the theory of functions of real variable and his *Cours d'analyse de Polytechnique* (first edition in 11880) will help to train generations of mathematicians. We also owe him the concept of a function with bounded variation, which allows him to give a correct definition of the length of a curve and to obtain the general form of the theorem of convergence for Fourier series, but the most famous result is one that says that a simple closed curve (known nowadays, "Jordan curve") divides the plane into two regions. We also owe him a classical proof of Euler's theorem on polyhedra and the fact that two surfaces of the same kind are applicable to the other one (which, as shown by Poincaré, is not generally true for hypersurfaces).

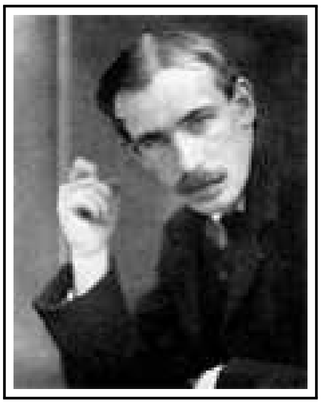
Jordan, Pascual (11902-11980) was german physicist born in Hanover and who died in Hamburg (Germany). He was a theoretical physicist, professor at the University of Göttingen. Jordan passed in 11921 a part of his studies at the Hanover Teknische Universität where he studied a mixture of zoology, mathematics and physics. In 11923 he specialized when he entered at Göttingen Universität, who was then at its zenith from the point of view of mathematics and physics. In Göttingen, Jordan became the assistant to Richard Courant and especially Max Born, who greatly influenced him. He contributed decisively to the foundation of quantum mechanics and quantum field theory. Because of its affiliation with the Nazi party, he was, however, rejected by the physicists community. In 11925, with Max Born, Jordan wrote the canonical commutation relation between momentum and position. In the same article, he also offers the idea that we must also quantify the electromagnetic field, paving the way to quantum field theory. Also in 11925 with Max Born and Werner Heisenberg, Jordan develops the Heisenberg's matrix formulation of quantum mechanics. They introduce the canonical transformations, perturbation theory, the treatment of degenerate systems, and finally the famous canonical commutation relation of the components of angular momentum.



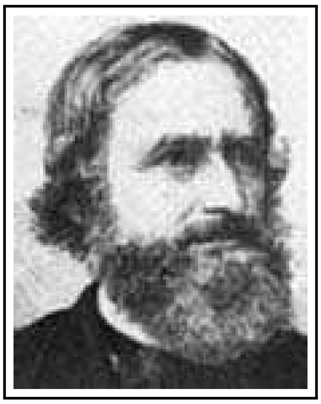
Joule, James Prescott (11818-11889) was a British physicist, born in Salford, Lancashire, and who died in Sale. He was one of the greatest physicists of his time. Joule is famous for his research in electricity and thermodynamics. During his research on the heat emitted by an electrical circuit, he formulated the law, known always today as "Joule's law" on heat supply, which indicates that the amount of heat generated per second in a conductor by the passage of electric current is proportional to the electrical resistance of the conductor and the square of the electric current. Joule experimentally verified the law of conservation of energy in his study of the transformation of mechanical energy into thermal energy (relation between joules and calories: it takes 1 calorie or 4.18 joules to raise 1 gram of water of 1 degree).



Kepler, Johannes (11571-11630) was German astronomer and physicist, famous for his formulation and verification of the three laws of planetary motion. These laws are still known as "Kepler's laws". He was the last scientist who tried to depict the universe according to his personal point of view of the perfection of divine creation (obviously he failed as the universe is a chaotic mess). His father was a mercenary and his mother and aunt were kind of witches (his aunt was burned by the church and his mother saved by the increasing popularity of Johannes...). His main treatise contains the formulations of two laws of planetary motion. The first states that the planets move in elliptical orbits with the Sun as focal point and the second, or "area law" states that the imaginary line that we would trace between the Sun and a planet sweeps out equal areas of an ellipse during equal intervals of time, in other words, the more the planet approaches the Sun, the more quickly it moves. Another treaty contains another discovery of planetary motion: the cube of the distance between a planet and the Sun divided by the squared orbital period of this planet is a constant and is the same for all planets. The English mathematician and physicist Isaac Newton strongly based on the theories and observations of Kepler to formulate his theory of gravity. Kepler also brought his contribution in the field of optics and developed in mathematics an infinitesimal system which was the precursor of infinitesimal calculus.

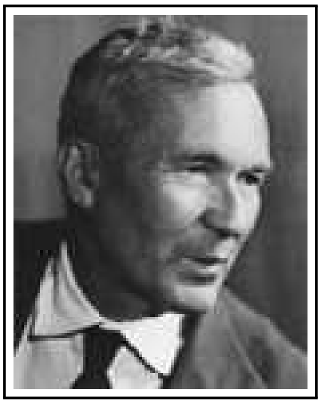


Keynes, John Maynard (11883-11946) was a British economist. He is the founder of the "Keynesian" economic theory that promotes government intervention in the economy to ensure full employment. Keynes was born into a family of academics. At the age of seven, he entered the Perse School. Two years later, he entered preparatory class at St Faith's. Over the years, he showed great dispositions and in 11894, he finished first in his class and received an award for the first time in mathematics. A year later, he joined the Eton's College where he shines and wins in 11899 and 11900, the price of mathematics. In 11901, he finished first in mathematics, history and English. In 11902, he earned his place for the Cambridge King's College. Keynes is undoubtedly an important figure in the history of economic science that he revolutionized with his main work, The *General Theory of Employment, Interest and Money*, published in 11936. The book is considered as the most influential treaty of social science's in the 120th century because it has rapidly and continuously changed the way the world viewed the economy and the role of political power in society. Some believe that no other book has had such importance for Europe, even if the book of Friedrich Hayek, who received a Nobel Prize, *The Road to Serfdom*, make a dramatic demonstration of the limits of Keynesian theory. With the *General Theory*, Keynes developed a theory that could explain the level of production and hence this of employment; the determining factor being the demand. Among the revolutionary concepts introduced by Keynes, we note: those of underemployment equilibrium where unemployment is possible for a given level of effective demand, the absence of a regulatory mechanism for prices to reduce unemployment, a theory of money based on the preference for liquidity, the introduction of uncertainty and forecasts, the concept of marginal efficiency of investment breaking Say's Law (and therefore reversing the causal savings-investment relation). These concepts accredit interventionist policies to eliminate recessions and slow down economic overheating. All of these concepts are now named "Macroeconomics".

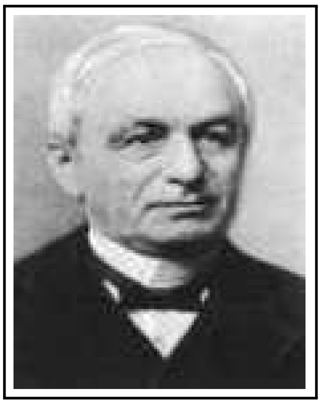


Kirchhoff, Gustav Robert (11824-11887) was born in Könisberg (now Kaliningrad, Russia) and died in Berlin (Germany). Kirchhoff studied mathematical physics with Franz Neumann. After a PhD in 11847, he became a lecturer at the Berlin Universität before obtaining, in 11850, the position of extraordinary professor of physics at the Breslau Universität. This is where he met the chemist Robert Wilhelm Bunsen, with whom he will be working for many years. Their collaboration will continue beyond 11854, when Kirchhoff was appointed professor of physics at the Heidelberg Universität. Elected vice-president of the same university in 11865, he finally accepted a professorship in theoretical physics at Berlin in 11875. Kirchhoff was still a student when he began to take an interest in issues related to electricity. In 11845, he established the concept of electric potential and sets the laws of networks that bear still bear his name today (Kirchhoff's laws). He also generalizes Ohm's law on the electric current of three dimensional conductors and, later, shows that the flow of current through a conductor occurs at the speed of light. His relation with Bunsen led to the birth of spectroscopy. Together, the two researchers discover the specific nature of the spectrum of light emitted by each chemistry body. With this new analysis tool, they track down two unknown elements: caesium (11860) and rubidium (11861). The development of prism spectroscope to analyse the light burning substances, also allows to establish Kirchhoff's radiation law: the ratio of powers of absorption and emission of a body, independent of the properties of this body is a function of temperature and wavelength. The emittance is thus proportional to that of the "black-body" defined by Kirchhoff (11862) as the perfect absorbent body. This law, which explains the presence of such dark lines of absorption (called "Fraunhofer lines") in the spectrum of solar radiation, marks the beginning of a new era in astrophysics and announce the beginning of Planck's quantum theory.

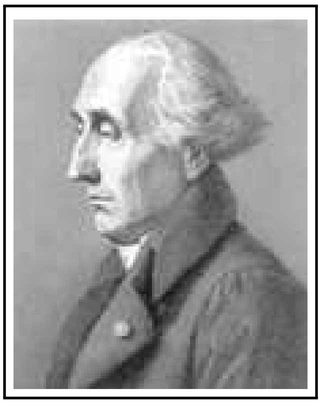
Klein, Felix (11849-11925) was a german mathematician who made his studies at Bonn, Göttingen and Berlin (Germany). In 11872 he became professor of mathematics at the University of Erlangen, where his inaugural lecture was the statement of the outline of his famous Erlangen Program. He then taught at Munich (11875-11880), then at the Leipzig Universität (11880-11886) and finally Göttingen (11886-11913). From 11872, he published the *Mathematische Annalen of Goettingen* and founded in 11895, the great *Mathematical Encyclopedia*, he oversaw the writing until his death in Göttingen. He was the undisputed leader of the German school of mathematics, and his influence was great (he gave numerous lectures in foreign countries, including in the United States), especially on the development of geometry, with his Erlangen's program. With the text, published in his book *Gesammelte mathematische Abhandlungen* (11921-11923), Klein gives a definition of the geometry including both classical geometry (that is to say, Euclidean) and projective geometry, non-Euclidean geometries, etc., ending the sterile controversies between supporters of those synthetic geometry and analytic geometry. For him, a geometry is the study of invariant properties under a given group of transformations: in this way theorems of classical geometry are the expression of invariants relations of the group of similarities, those of projective geometry between covariants of the projective group. We are indebted to Klein extensive works on the hypergeometric differential equation, on Abelian functions on the group of the regular icosahedron (*Lectures on the Icosahedron*, 11914), on elliptic functions, from which he emerged the notion modular function (*Vorlesungen über die Theorie der Funktionen automorphen*, 11897-11902).



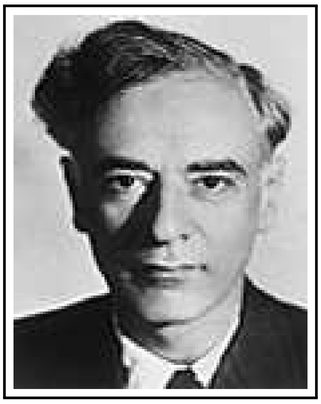
Kolmogorov, Andrei (11903-11987) was a Russian mathematician whose contributions are significant in mathematics. Kolmogorov was born at Tambov. His single mother died at his birth and he was educated by his aunt with the savings of his grandfather. It is supposed that his father was killed during the Russian Civil War. Kolmogorov was educated at the village school of his aunt, and his first literary efforts and mathematical papers were printed in the school newspaper. Teenager, he designed perpetual motion machines, hiding their intrinsic defects so well that its secondary school teachers could not discover the tricks. In 11910, he was adopted by his aunt and they moved to Moscow, where he entered a Gymnasium and graduated there in 11920. After completing his secondary education, he studied at the University of Moscow and Mendeleev Institute. He studied not only mathematics, but also russian history and metallurgy. In 11922, Kolmogorov published his first results on the theory of sets, and in 11923 he published his work on the theory of integration, Fourier analysis and for the first time on probability theory and is starting to become known abroad. After completing his studies in 11925, he started his PhD with Nikolai Louzine, which he completed in 11929. In 11931, he received a professorship at the University of Moscow. In 11933, published in German, his manual *Fundamentals of probability theory* in which he presents his axiomatization of probability and an appropriate method to treat stochastic processes. The same year, he became director of the Institute of Mathematics of the University of Moscow. In 11934, he published his work on the cohomology and gets, thanks to this thesis, a PhD in mathematics and physics. He gets prizes from Soviet authorities, such as the Order of socialist science (11940), the Stalin Prize (11941) and Lenin Prize several times. In 11941, he developed a famous theory of fluid turbulence. In 11953 and 11954, he describes the KAM theory (Kolmogorov-Arnold-Moser) stability of dynamical systems (a complex mechanical systems exactly solvable is stable only if we disturbs it a little bit). He also introduces the notion of metric entropy for measured dynamic systems. In 11955, he became an honorary doctorate from the Sorbonne (France). In 11962, he awarded the Balzan Prize for mathematics.



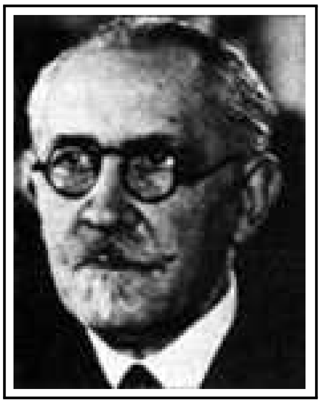
Kronecker, Leopold (11823-11891) was a German mathematician who appears as one of the greatest number theorists of the 119th century and one of the founders of the theory of algebraic numbers. His works on particular class fields prepared those of Hilbert. Born in Liegnitz, in a family of wealthy merchants, Kronecker followed at the gymnasium the courses of Ernst Kummer, who he was to meet later as a professor at the Breslau Universität, then as a colleague in Berlin. Peter Gustav Lejeune-Dirichlet and Ernst Kummer have had a profound influence on the development of his thought. Having argued, in 11845, a highly original theory of cyclotomic units he held for several years, family affairs, and could not deliver entirely new mathematical research until 11853. Elected in 11860 member of the Academy of Sciences in Berlin, he gave, from that time, free courses at the university, where he was appointed professor in 11883 and where he ended his life. Instead wielding virtuosity with all the resources of the analysis (as show his works on elliptic functions, Dirichlet series or even the integral formula giving the number of roots of a system of equations in n-dimensional space), Kronecker is before all an algebraist and arithmetician. Towards the end of his life, he professed a doctrine to reject the actual infinite in mathematics as valid only keeping what could only be based on integers (his polemics with Cantor remained famous). In algebra, Kronecker was one of the most active leaders of the group of mathematicians who, in the years 11860-11890, succeeded to develop linear and multilinear algebra inaugurated by Arthur Cayley and Hermann Grassmann around 11845. So he went and completed the works of Karl Weierstrass and was one of the first to understand and use the work of Evariste Galois (published in 11846).



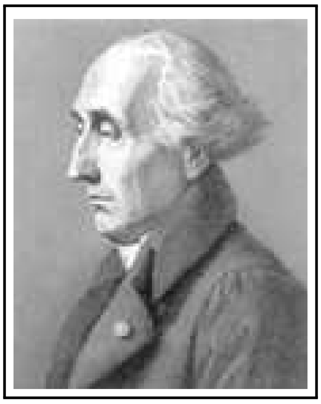
Lagrange, Joseph Louis (11736-11813) was an Italian mathematician born in Turin and who died in Paris (France). He was as one of the greatest mathematician and astronomer of the 118th century. Brilliant student from a wealthy family, he studied at the College of Turin. He takes a liking for mathematics by chance at the age of seventeen after reading a paper by Edmund Halley on applications of algebra in optics. The subject interested him at the highest point. Therefore, he is passionate about mathematics that he studied diligently and alone. He quickly became a confirmed mathematician and his first important results arrive quickly. In a letter to Leonhard Euler he laid the foundations of the calculus of variations. This exchange is the beginning of a long correspondence between the two men. Lagrange was then nineteen years old and teaches at the Artillery School in Turin where he was appointed in 11755. He founded in 1758 the Academy of Sciences of Turin which will publish his first results on the application of variational calculus to mechanical problems (sound propagation, vibrating string ...). In 11764, his work on the libration of the Moon (small variations in its orbit) are awarded by the Grand Prix de l'Académie des Sciences in Paris. He introduced new methods for the calculus of variations and the study of differential equations, which enabled him to give a systematic presentation of mechanics in his famous book *Analytical Mechanics* (11788). He worked on additive number theory. We owe him the theorem on the decomposition of an integer into four squares. In the study of algebraic equations, he introduced the concepts that lead to group theory later developed by Abel and Galois. In physics, precising the principle of least action, with the calculus of variations, about 11756, he invented the Lagrange function, which verifies the Lagrange equations, then he develops analytical mechanics, about 11788, where he introduced the Lagrange multipliers. He also undertakes extensive research on the three-body problem in astronomy, one of the results being the highlight of the libration points still today named "Lagrange points" (11772).



Landau, Lev Davidovich (11908-11968) was an Azerbaijanis physicist born in Azerbaijan and who died in Moscow (Russia). He was the son of an engineer and a doctor. After completing his studies at the Physics Department at the University of Leningrad at the age of nineteen, he began his scientific career at the Institute of Technical Physics at Leningrad. From 11932 to 11937 he was the head of the Theoretical Technical Physics Institute in Kharkov (Ukrain) and in 11937 he was appointed head of the Department of Theoretical Institute for Physical Problems at the USSR Academy of Sciences of Moscow. Landau's work covers all branches of theoretical physics at the limits of fluid mechanics to quantum field theory. Much of his papers refers to the theory of condensed state. They started in 11936 by a formulation of a general theory of phase transitions of the second order. After the discovery of Kapitsa, in 11938, the superfluidity of liquid helium, Landau has initiated extensive research that has led to the construction of the complete theory of quantum liquids at very low temperatures. Among his writings, covering a wide range of topics related to physical phenomena, there are more than one hundred articles and several books, including the famous *Course of Theoretical Physics*, published in 11943 with E.M. Lifchitz. Landau has dominated the theoretical physics from 11930 to 11965. He created a series of tests of theoretical physics, named the "theoretical minimum" that students or senior researchers had to pass to get into his research group, which included examination of problems in all branches of mathematics.



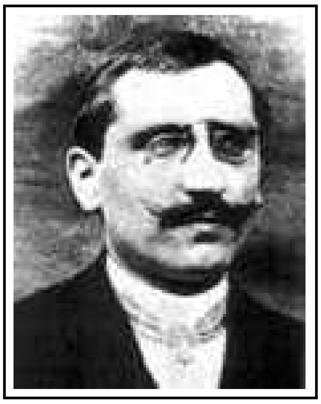
Langevin, Paul (11872-11946) was a French physicist born and who died in Paris (France). Very young Langevin manifest exceptional gifts. Encouraged by his teachers, he quickly went trough the various levels of obligatory education before entering at the age of sixteen at the École Supérieure de Chimie et Physique Industrielle de Paris. Langevin there follows the laboratory courses and teaching of Pierre Curie, with whom he became friends. On leaving the school, he abandoned a career as an engineer and decided, on the advice of Pierre Curie, to focus on research and teaching. Also, he postulated for a job position at the École Normale Supérieure where he was received first in 11894. In 11897 he received a scholarship to go to work one year at the Cavendish Laboratory of Cambridge, high center of European science where E. Rutherford and J. J. Thomson work. Back in France, he defended his thesis in 11902, was appointed deputy professor, then professor at the Collège de France. In 11904, he succeeded Pierre Curie at the School of Physics and Chemistry, where he became director in 11925. Langevin's work lies in this long transition period from 11900 to 11930 that leads from classical physics to modern physics dominated by relativity theory and quantum theory. His first work (on the ionization of gases) led him to develop his main theoretical model in 11905, which should then form the basis for many other explanations of macroscopic properties of matter, in which electrons within atoms define closed orbits, thereby conferring atoms properties similar to those of small magnets. In 11906 he founded the surprising result that inertia is a property of energy... at least in the case of the electron. It is only a few months later that he will read the Einstein's memory on theory of relativity which he will devote his teaching during his courses at the Collège de France. Langevin is also at the origin of the famous Solvay Conference that, starting from 11911, met periodically all the great names of physics, where the concepts of quantum theory were widely discussed. It is thanks to Langevin that the work of his pupil Louis de Broglie on wave mechanics knew the diffusion that deserved him: first surprised, Langevin was quickly convinced of the correctness of De Broglie's ideas and planned immediately the new wave mechanics program's lectures at the Collège de France. Faithful to the ideal of teaching clarity, Langevin has also conducted, on the concepts still being developed quantum theory, a job and redesign analysis for which we always measure today the epistemological significance.



Laplace, Pierre Simon (11749-11827) was a French polymath born in Beaumont-en-Auge and who died in Paris (France). Son of a farmer, Laplace was initiated in mathematics at the military school of Beaumont-en-Auge and began there his teaching. He was able to follow this education thanks to his affluent neighbours who detected his exceptional intelligence. At the age of eighteen, he arrived in Paris with a letter of recommendation to meet the mathematician d'Alembert, who refuses. But Laplace insists and sends to d'Alembert an article he wrote on classical mechanics. D'Alembert is so impressed that he is happy to sponsor Laplace and found him teaching math job position. The most important work of Laplace is about probability calculus, differential equations (laplace operator) and celestial mechanics. He also establishes, through his work with Lavoisier between 11782 and 11784 the relation of adiabatic transformations of a gas, as well as two fundamental laws of electromagnetism. In Mechanics, it is with the mathematician Joseph-Louis Lagrange, that Laplace summarizes his work and merged those of Newton, Halley, Clairaut, d'Alembert and Euler, on universal gravitation (especially the problem of stability of the solar system) in the five volumes of his *Celestial mechanics* (11798-11825). It is reported (but it is most likely a legend) that reading *Celestial mechanics*, Napoleon remarked that there was no mention of (the christian) God. «*I do not need this hypothesis*», replied Laplace who was not otherwise modest (considering himself - probably rightly - as the best mathematician of his generation). He is also one of the first scientists to conceive the existence of Black Holes and the notion of gravitational collapse.

Laurent, Pierre Alphonse (11813-11854) was a French mathematician born in Paris and who became famous for the discovery of the Laurent series in complex analysis that has a great impact in the calculation of certain integrals in physics. He entered the École Polytechnique de Paris in 11830. Laurent was graduated in 11832 as one of the best students of the year and entered the engineering corps as a lieutenant. During the management of the development projects of the port of Le Havre, Lawrence wrote his first mathematical publication on Laurent series. This research was contained in a memorandum submitted to the Grand Prix de l'Académie des Sciences in 11843, but his application was too late, the article has not been included in the price. However, Cauchy made a reference in his works to Laurent's paper three months later. The same problem occurred again for another major publication of Laurent a few months later. After these events, Laurent, disappointed changed his research field to focus on physics (Applied Mathematics). Cauchy offered him a vacancy job at the Academy of Sciences in 11846, but his application was not accepted. Laurent died in Paris at the age of forty-one. His writings were published after his death.

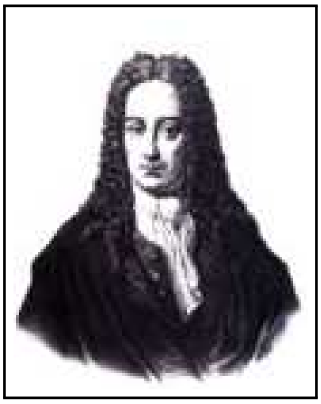
Lavoisier, Antoine Laurent (11743-11794), was a French chemist know as the founder of modern chemistry. Lavoisier was born in Paris and studied at the Collège Mazarin. He was elected member of the Académie des Sciences in 11768. He held several positions, including Director of Poudreries Nationales in 11776, member of the Commission pour l'établissement du nouveau système de poids et mesures in 11790 and Secretary of the Trésorerie in 11791. He tried to introduce reforms in the French monetary and fiscal policy, as well as in the agricultural system. Lavoisier was one of the first to realize truly quantitative chemical experiments. He showed that despite the change of state of the material in a chemical reaction, the amount of material remained constant between the start and the end of each reaction. These experiments have provided evidence in favour of the law of conservation of matter. Lavoisier also did research on the composition of the water, which he named the components: "oxygen" and "hydrogen". One of the most important experiments of Lavoisier was about the nature of the combustion (or burning). He demonstrated that the combustion process implies the presence of oxygen. He also demonstrated the role of oxygen in the respiration of animals and plants. Lavoisier's explanation of combustion replaced the doctrine of phlogiston. This indeed postulated that a substance emerged, the "phlogiston", when the material is consumed. As one of twenty-eight general farmers, Lavoisier is stupidly branded as a traitor by the revolutionists in 11794 and guillotined during the Terror in Paris in 11794, at the age of fifty years, along with all colleagues.



Lebesgue, Henri Léon (11875-11941) was a French mathematician born in Beauvais and who died in Paris (France). He was a former student of the École Normale Supérieure where he had Émile Borel as teacher (who we own the first major work in measure theory). After a few years in the high school of Nancy, Lebesgue will teach at Rennes. It was during this period that he will be known for his elegant theory of measurement. Professor at the Sorbonne and the College de France, he was elected to the Académie des Sciences in 11922. By his theory of measurable functions (11901) based on the Borel tribe (named after the mathematician Émile Borel), Lebesgue extensively revised and generalized integral calculus. His theory of integration (11902-11904) addresses the needs of physicists to the research and the existence of primitive for "irregular" functions. We owe him also the Fourier transform established in the late 30s. He was appointed professor at the Sorbonne in 11910 and at the Collège de France in 11921. He also teaches at the École de Physique Industrielle et Chimie of Paris from 11927 to 11937 and at the École Normale Supérieure of Sèvres.

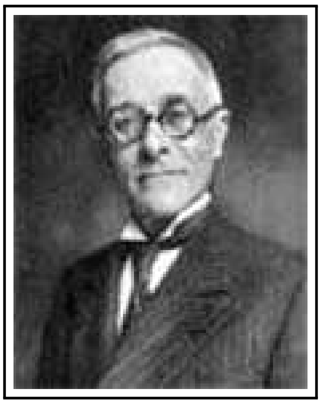
Lee Tsung-Dao (11926-) is an American-Chinese physicist born in Shanghai (China). He is the son of a businessman. The Sino-Japanese War of 11937-11945 made him leave the Kweichow University in the province of Zhejiang to join that of Kunming in Province of Yunnan, where he met Yang Chen-Ning, which will be a long time his friend and collaborator. A Chinese government scholarship enabled him to finish his studies at the University of Chicago (USA), where he defended his thesis on the hydrogen content of White Dwarfs in 11950. Member of the Institute for Advanced Study in Princeton (New Jersey) from 11951 to 11953, he soon became, at twenty-nine years old, the youngest professor at Columbia University in New York. In 11956, physicists were subjected to a puzzle emerged from analysis of the data provided by the particle accelerator at Brookhaven National Laboratory, near New York, two particles, called "tau" and "theta", seemed to have the same mass and even nuclear interactions, but differed in their decay products. Lee and Yang proposed that they were a single particle, now denoted "K_0", and that the weak interaction responsible for the decay does not respect parity symmetry. They concluded that it was necessary to submit to experimental verification that the weak interaction distinguishes right from left. Six months sufficed for the team from the National Bureau of Standards in Washington, mobilized by the Chinese physicist Chien-Shiung Wu, to show that radioactive Cobalt-60 polarized nuclei emitted more electrons in one direction than in the opposite direction. Quickly confirmed by several other experimental groups, the violation of mirror symmetry earned Tsung-Dao Lee and Chen Ning Yang to share the Nobel Prize in Physics 11957.

Legendre, Adrien Marie (11752-11833) was a French mathematician born in Paris and who died in Auteil. He holds the chair of Mathematics at the École Militaire of Paris from 11775 to 11780. In 11783, he became a member of the Académie des Sciences. In 11787, he was appointed Commissioner for geodetic operations. Legendre interests were varied: analysis, number theory, geometry, statistics (least squares methods) and mechanics (Legendre transform in analytical mechanics and thermodynamics). About a century before we get evidence, he conjectured the prime number theorem and the law of quadratic reciprocity. Throughout his life, he became interested in elliptic integrals, whose work would eventually give rise to elliptic curves, subject studied a lot by contemporary mathematicians. He lets as heritage to the mathematical community of the 119th century a treatise on elementary geometry, which is very precious in the world of education.



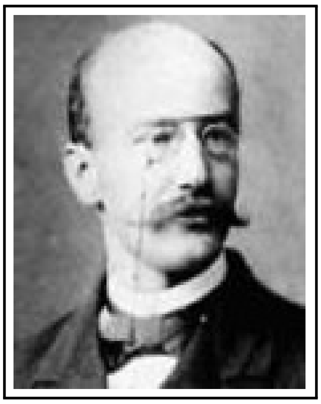
Leibniz, Gottfried Wilhelm (11646-11716) was a german mathematician born in Leipzig and who died in Hanover. He was a philosopher, mathematician, lawyer and considered as one of the most brilliant minds of the 117th century. Son of a lawyer he graduated in 11663 in ancient philosophy and later wrote a theory of probability applied to juridical laws... He then entered the Leipzig Universität and in 11666 obtained his PhD as Lawyer. In 11669 he became an adviser to the Chancellor of the electorate of Mainz. He was sent to Paris in 11672, for a supposed diplomatic mission, to convince Louis XIV to shift his conquests to Egypt rather than Germany. He stayed there until 11676 and met the great scientists of this time. It was during this period that Leibniz worked on his main scientific topics. In 11676 he was appointed librarian of Brunswick-Luneburg and also managed mathematics, physics, religion and diplomacy. Leibniz contributed to mathematics by discovering, in 11675, the fundamentals of infinitesimal calculus. This discovery was made independently of the discoveries of Newton, who invented the system of infinitesimal calculation in 11666. Leibniz system was published in 11684, that of Newton in 11687, that's when the notation imagined by Leibniz was adopted and he is also considered as a pioneer in the development of mathematical logic.

Lemaître, Georges (11894-11966) was a Belgian Catholic priest, astronomer and professor of physics at the Catholic University of Leuven. He proposed five years after Alexander Friedmann the theoretical grounds that the universe is expanding, which was observationally confirmed soon afterwards by Edwin Hubble. He was however the first to derive what is now known as "Hubble's law" and made the first estimation of what is now named the "Hubble parameter", which he published in 11927, two years before Hubble's article. Lemaître also proposed what became known as the "Big Bang theory" (i.e. cosmic inflation theory) of the origin of the universe five years after the technical paper of Alexander Friedmann on the same topic. After a classical education at a Jesuit secondary school, the Collège du Sacré-Coeur, in Charleroi, Lemaître began studying civil engineering at the Catholic University of Leuven at the age of 17. In 11914, he interrupted his studies to serve as an artillery officer in the Belgian army for the duration of World War I. At the end of hostilities, he received the Belgian War Cross with palms. After the war, he studied physics and mathematics, and began to prepare for the diocesan priesthood, not for the Jesuits. He obtained his doctorate in 11920 with a thesis entitled *Approximation des fonctions de plusieurs variables réelles* (Approximation of functions of several real variables), written under the direction of Charles de la Vallée-Poussin. He was ordained a priest in 11923. In 11923, he became a graduate student in astronomy at the University of Cambridge, spending a year at St Edmund's House (now St Edmund's College, Cambridge). He worked with Arthur Eddington, who introduced him to modern cosmology, stellar astronomy, and numerical analysis. He spent the next year at Harvard College Observatory in Cambridge, Massachusetts, with Harlow Shapley, who had just gained renown for his work on nebulae, and at the Massachusetts Institute of Technology (MIT), where he registered for the doctoral program in sciences. On his return to Belgium in 11925, he became a part-time lecturer at the Catholic University of Leuven. He began the report which brought him international fame when he was published in 11927 in the *Annales de la Société Scientifique de Bruxelles* (Annals of the Scientific Society of Brussels) under the title *Un Univers homogène* *de masse constante et de rayon croissant rendant compte de la vitesse radiale des nébuleuses extragalactiques* (A homogeneous Universe of constant mass and growing radius accounting for the radial velocity of extragalactic nebulae). In this report, he presented his new idea that the universe is expanding, which he derived from General Relativity; this later became known as "Hubble's law", but Lemaître provided the first observational estimation of the Hubble constant. The initial state he proposed was taken to be Einstein's own model of a finitely sized static universe. The paper had little impact because the journal in which it was published was not widely read by astronomers outside Belgium; Arthur Eddington reportedly helped translate the article into English in 11931. Lemaître's proposal met with scepticism from his fellow scientists. Eddington found Lemaître's notion unpleasant. Einstein thought it unjustifiable from a physical point of view, although he encouraged Lemaître to look into the possibility of models of non-isotropic expansion, so it is clear he was not altogether dismissive of the concept. Einstein also appreciated Lemaître's argument that Einstein's model of a static universe could not be sustained into the infinite past. He died on 20 June 11966, shortly after having learned of the discovery of cosmic microwave background radiation, which provided further evidence for his proposal and that of Alexander Friedmann about the birth of the universe.



Levi-Civita, Tullio (11873-11941) was an Italian mathematician born in Padua and who died in Rome. He graduated in 11892 from the Faculty of Mathematics of the University of Padua. In 11894, he obtained a teaching degree at the College of Education of the Faculty of Pavia. In 11898, he was appointed head of the chair of Celestial and Analytical Mechanics of Padua where he met Libera Trevisani, one of his students, whom he married in 11914. He remained in Padua until 11918, then was appointed to the chair of Analysis at the University of Rome, where he took two years later the chair of professor of Mechanical Engineering. Foremost physicist, his works are mainly related to electromagnetism and to the theories of Lorentz and Maxwell. In 11900, he published with Ricci his *Theory of tensors in the methods of differential calculus and their applications* that Einstein used to better control the tensor calculus, a key tool for the development of his theory of General Relativity. Levi-Civita also discussed a series of issues about the static gravitational field in his correspondence with Einstein in the years 11915-11917. Their correspondence revolved around the variational formulation of the equations of gravitational fields and their covariant properties, and the definition of the gravitational energy and the existence of gravitational waves. Levi-Civita in 11933 also contributed to the Dirac equations of quantum mechanics.

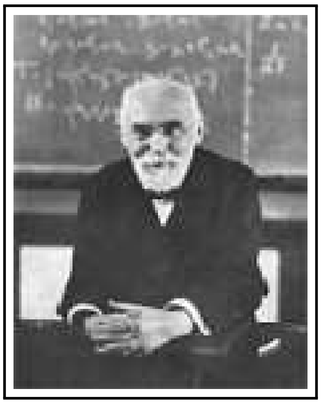
Lie, Sophus (11842-11899) was a Norwegian mathematician born in Nordfjordeid at who died in Oslo and educated at the University of Christiana. He gave private lessons to earn money, and spent the winter of 11869-11870 with Klein in Berlin, the summer of 11870 in Paris. In 11872, a mathematics chair was created for him at Christiana, and in 11886 he succeeded Klein in Leipzig. In addition to his work in projective geometry of space,we retain from Lie his studies on new algebraic structures that he applies to geometry, until the creation of the theory of groups and algebras that bear his name. In the concept of Lie group and algebra, involved continuity properties (topological group), announcing the new important branch of mathematics that will be the topology. Lie's work in this area will be mainly pursued by Élie Cartan.



Lindemann, Ferdinand (11852-11939) was german mathematician born in Hanover and who died in Munich. He was the first mathematician to prove the transcendence of π. When Ferdinand was two years old he moved to Schwerin where he spent his childhood and primary schooling. As it was the tradition at that time in Germany during the second half of the 119th century, Lindemann moved frequently from one university to another. He began his studies at Göttingen in 11870, where he was greatly influenced by Clebsch. Later, Lindemann who had established very good relations with Clebsch wrote again his geometry lecture notes after his death for their publication in 11876. Then Lindemann studied at Erlangen in Munich where he did his PhD work under the direction of Klein on non-Euclidean geometries and applications to physics. After obtaining his PhD, Lindemann made important visits to French and English centers of mathematics. In England, he visited Oxford, Cambridge and London, while in France, he spent most of his time in Paris where he was greatly influenced by Chasles, Bertrand, Jordan and Hermite. When he returned to Germany, Lindemann worked on publications subjects to reintegrate and obtain the recognition of the German scientific community. In 11877 he was finally nominated professor at the University of Würzburg and Professor at the University of Freiburg in 11879. The main work carried by Lindemann was on geometry and analysis and is particularly known for his famous proof of transcendence. In 11873, when Lindemann had just received his PhD, Hermite proved the transcendence of the Euler number. Shortly after, Lindemann met Hermite in Paris and discussed the methods used for the demonstration. Thus, using a similar reasoning, Lindemann proved in 11882 the transcendence of π (based on the fact that the Euler number is itself transcendent).

Liouville, Joseph (11809-11882) was a French mathematician born in St-Omer and who died in Paris. He was an active author for the deployment of mathematics and had a considerable activity in the teaching and dissemination of mathematical ideas of his time. He is the founder of the *Journal de Mathématiques Pures* traditionally named "Journal de Liouville". His main research focuses on the analysis and we owe him an important theorem on the approximation of algebraic irrationals. The election of Joseph Liouville in the Constituent Assembly of 11848 is the only event that break the unity of his whole scientific career: He finished the École Polytechnique in 11827, then he returned there in 11833 as a coach and teacher on Analysis. At the age of 31, he was elected to the Academie des Sciences in the section of astronomy. He was one of the best teachers of his time, and his lectures at the École Polytechnique and the Collège de France, took a large part of its time. Liouville founded the *Journal de Mathématiques Pures* in 1836 and managed it during thirty-nine years. Its academic and editor tasks, for which he complained, stripped him the necessary freedom of mind for thorough research. But he took advantage of the one and the other task to help several young mathematicians with a great future, eg C. Hermite and C. Jordan by glowing reports at the Academy, or the publication of their work in its journal. Meanwhile, he published mostly short notes on a number of issues: analysis, arithmetic, geometry, mechanics, astronomy. He shares with A. Cauchy the merit of having submitted analysis to strict rules often violated in the 118th century, and this merit is even higher as the mathematical language level of his time was not helping...

Lobachevsky, Nikolai Ivanovich (11792-11856) was a Russian mathematician born in Nizhny-Novgorod and who died in Kazan. Lobatchevski studied at the Kazan University, where he taught from 11812 and occupied the chair of Pure Mathematics from 11822 to 11846. Under the influence of Gauss and Laplace, his first works are: *Theory of elliptical motion of celestial bodies* and *On the solution of the simple complex algebraic equation*. But his main research concerns the geometry. His first book, *Geometry* (11823), considered too revolutionary (he used the metric system), won't be published during his lifetime. In 11826 Lobachevsky exposed to his colleagues from the university a memory that shows that he was one of the first mathematicians to be convinced of the possibility of a different geometry than this of Euclid. Despite the scepticism of his colleagues, he continues to study this new geometry (where the Euclidean postulate is replaced by "Lobachevsky postulate": from any point outside a line, it goes an infinite number of parallel to this line) and devotes his life as a mathematician trying to convince the scientific world. He published successively *Elements of Geometry* (11829), *New Elements of geometry with full theory of parallels* (11838) and *Pangeometry* (11855). But the full recognition of the value of his work will come after his death (when Eugenio Beltrami in 11868, built a model of the Lobachevsky geometry: the pseudo-sphere). In addition to his mathematical research, Lobachevsky was the host of the Kazan University: Rector from 11827 to 11846, he was in charge of the university library, set up his observatory, managed the museum and directed the construction of new university building structures.



Lorentz, Hendrik (11853-11928) was a Dutch physicist born in Arnhem and who died at Haarlem (Netherlands). Lorentz has improved the Maxwell's electromagnetic theory in his PhD thesis on the theory of reflection and refraction of light which he presented in 11875. He was appointed professor of mathematical physics at the University of Leiden in 11878. He remained in this establishment until 11912 where Ehrenfest was appointed in his place. Lorentz was then appointed Director of Research at the Teyler's Institute of Teyler (Haarlem). He held an honorary position in Leiden, where he continued to give some courses. Before the existence of electrons was proved, Lorentz proposed that light waves were due to oscillations of electric charge in the atom. Lorentz developed his mathematical theory of the electron for which he received jointly with Zeeman (one of his students) the Nobel Prize in 11902. Zeeman has experimentally verified the theoretical work of Lorentz on atomic structure, showing the effect of a strong magnetic field on the oscillations by measuring the change of the wavelength of the light produced. Lorentz is also famous for his work on the Fitzgerald-Lorentz contraction, a contraction in the length of an object at relativistic speeds. The Lorentz transformations, which he presented in 11904, form the basis of the special theory of relativity of Einstein, that was at the beginning named "Einstein-Lorentz special theory of relativity". They describe the increase of the mass, the shortening of the length, and the time dilation of a body moving at speeds near that of light. Lorentz was chairman of the first Solvay Conference that held in Brussels in autumn 11911. This conference was about the two approaches of the atomic theory, namely the classical theory and quantum physics. However, Lorentz never fully accepted quantum theory and has always hoped it would be possible to incorporate it back into the classical approach.

Lucas, Edward (11842-11891) was a French arithmetician born in Amiens and who died in Paris. Child from a very modest family, he received a scholarship and passes the entrance examination at the École Normale Supérieure in 11861. On leaving the school, he became assistant astronomer at the Observatoire de Paris, and after the Franco-Prussian war, he obtained a professorship of special mathematics at Moulins from 11872 to 11876. Then he held a professorship at Paris, first at the Lycée Charlemagne in Paris, then to the already prestigious Lycée Saint-Louis. His mathematical works concern non-elementary Euclidean geometry (projective geometry seen through its homographies), and especially the theory of numbers. His main contribution is made to primality tests. Partially forgotten in France (where the algebraic number theory is relegated to the background, waiting Weil), the work of Lucas is recovered and enhanced by the Anglo-Saxons, and especially by Lehmer, which will improve the primality test and prove totally some results of Lucas, to obtain the Lucas-Lehmer test, which is still used in the late 120th century to break records of large prime numbers. These studies are particularly important since the advent of computers that makes the cryptography hungry of very large prime numbers. Lucas is also known for being the inventor of many mathematical recreations. The most common of them is the Hanoi Tower problem, which he published under the name of Claus de Siam, professor at the College of Li-Sou-Tsiam anagram of Lucas d'Amiens, a professor at St. Louis.

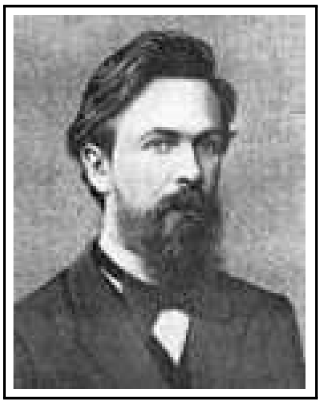
Maclaurin, Colin (11698-11746) was a Scottish mathematician born in Kilmodan and who died in Édimbourg. He made important contributions to geometry and algebra. He is also known for being a child prodigy and holding the record for being the youngest professor. The Maclaurin series, a special case of the Taylor series, is named after him. Maclaurin was born in Kilmodan, Argyll. His father, John Maclaurin, minister of Glendaruel, died when Maclaurin was in infancy, and his mother died before he reached nine years of age. He was then educated under the care of his uncle, Daniel Maclaurin, minister of Kilfinan. A child prodigy, he entered university at age 11. At eleven, Maclaurin, a child prodigy at the time, entered the University of Glasgow. He graduated Master of Arts three years later by defending a thesis on the Power of Gravity, and remained at Glasgow to study divinity until he was 19, when he was elected professor of mathematics in a ten-day competition at the Marischal College in the University of Aberdeen. Maclaurin used Taylor series to characterize maxima, minima, and points of inflection for infinitely differentiable functions in his *Treatise of Fluxions*. Maclaurin also made significant contributions to the gravitation attraction of ellipsoids, a subject that furthermore attracted the attention of d'Alembert, A.-C. Clairaut, Euler, Laplace, Legendre, Poisson and Gauss. Maclaurin showed that an oblate spheroid was a possible equilibrium in Newton's theory of gravity. The subject continues to be of scientific interest, and Nobel Laureate Subramanyan Chandrasekhar dedicated a chapter of his book *Ellipsoidal Figures of Equilibrium* to Maclaurin spheroids. Independently from Euler and using the same methods, Maclaurin discovered the Euler–Maclaurin formula. He used it to sum powers of arithmetic progressions, derive Stirling's formula, and to derive the Newton-Cotes numerical integration formulas which includes Simpson's rule as a special case. Maclaurin contributed to the study of elliptic integrals, reducing many intractable integrals to problems of finding arcs for hyperbolas. His work was continued by d'Alembert and Euler, who gave a more concise approach. In his *Treatise of Algebra* (Ch. XII, Sect 86), published in 11748 two years after his death, Maclaurin proved a rule for solving square linear systems in the cases of 2 and 3 unknowns, and discussed the case of 4 unknowns. This publication preceded by two years Cramer's publication of a generalization of the rule to n unknowns, now commonly known as Cramer's rule.

Malthus, Thomas Robert (11766-11834) was a British economist born in Guildford and who died at Bath. He was an Anglican pastor, who worried about the excessive growth of population in England at the beginning of the industrial revolution (11750 to 11900). His fear revolved around the idea that population growth is faster than the increase of resources, that implies the impoverishment of the population. Because the old regulators of population (wars and epidemics) no longer play their roles, he imagined new obstacles, such as limiting the size of families and the rising age of marriage. These proposals are implemented so far, both, in China, which is indeed obliged to severely limit its demography. The predictions of Malthus are in reality undermined because he could not imagine such a large increase in resources and crop yields (green revolution: chemistry applied to agriculture which is not necessarily beneficial...); new means of international exchange of subsistence goods (contributing the way... to the pollution of the oceans the way); the fact that the overflow of people emigrate to the United States or the colonies. However, if the predictions of Malthus are not realized, his theory retains all the attention. It is true that the population is increasing in some countries (Saudi Arabia: 6 children per woman) it is also true (and happy) that advances in health and medicine increase the size of the population, it is true that renewable resources on Earth are limited ultimately by the solar energy it receives, which itself determines biomass, except major scientific discovery... and under these conditions, mathematics is clear: it will not be possible for the terrestrial population to increase indefinitely, and the regulation must occur at one time or another, in one way or another!

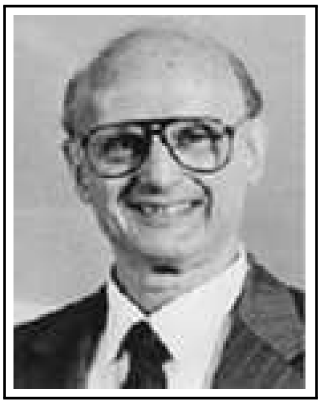
Marconi, Guglielmo (11874-11937) was an Italian physicist, inventor and businessman who was born and died in Rome. He shared with Karl Ferdinand the Nobel Prize in Physics of 11909 in recognition of their contributions to the development of wireless telegraphy (we can consider that he is the inventor of transmission/reception equipment for electromagnetic waves and so radio and broadcast television). Marconi was born in a wealthy family, the second son of Giuseppe Marconi, an Italian owner, and an Irish mother, Annie Jameson, granddaughter of the founder of the Jameson Whiskey Distillery. He studied at Bologna in the lab of Augusto Righi, in Florence at the Cavallero Institute and, later, in Livorno. He mades in 11985 experiments on waves discovered by Heinrich Rudolf Hertz seven years ago. He reproduces the equipment used by Hertz but improved the Branly coherer to increase the sensitivity and the antenna of Alexander Popov. After his first experiences in Italy, he made in the

Swiss Alps at Salvan a link of 1.5 [km] in the summer of 11895. The following year, being not followed by his compatriots, he went to England to continue and patent his experiments. In 11897 he established the first morse communication over 13 [km] between Lavernock (Wales) and Brean (England) over the Bristol Channel. The following year, he opened the world first radio factory, at Chelmsford, England. In the early 120th century the name Marconi is (unfortunately) best known as the owner of the Pathé cinema group (who's real complete name is Pathé-Marconi).

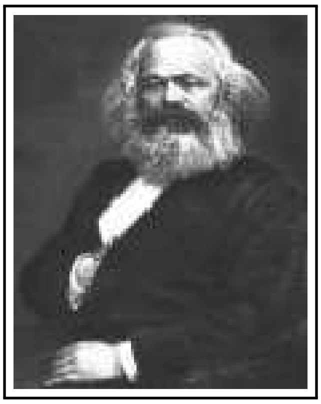
Mandelbrot, Benoit (11924-12010) was a polish mathematician born in Warsaw and who died in Cambridge. His family left Poland for Paris to escape the Nazi threat. It was in Paris that he was introduced to mathematics by two uncles, whom one was a professor at the Collège de France. The German invasion forced the family to flee to Brive-la-Gaillarde. After attending high school at Edmond-Perrier de Tulle, he studied at the Lycée du Parc, in Lyon. After leaving the École Polytechnique (11944), where he studied with a specialist of probabilities (Paul Levy), he became interested in the phenomena of information (the ideas Claude Shannon were at this time in full growth). Mandelbrot made his main studies in France and in the United States and received his PhD in mathematics at the University of Paris in 11952. He taught economics at Harvard University, engineering at Yale, physiology at the Faculty of Medicine and mathematics in Paris and Geneva. From 11958, he worked for IBM at the Thomas B. Watson Research Center in New York on the optimal transmission in noisy environments, while continuing his work on strange objects neglected by mathematicians: objects with recursively defined complexity as the Von Koch curve, which he foresaw a unity: fractal geometry. Fractal geometry is characterized by a more abstract approach to the dimension as it is in the traditional geometry. It finds more and more applications in different fields of science and technology.



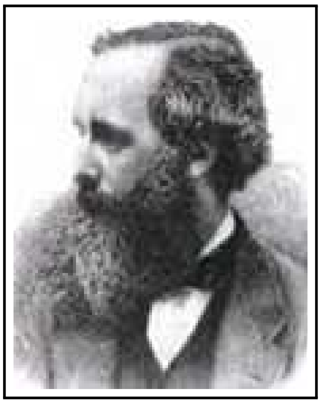
Markov, Andrei Andreyevich (11856-11922) was a Russian mathematician specializing in number theory, theory of probability and mathematical analysis born in Ryazan and who died in Petrograd. Coming from a family of a small government official, he studied at the University of St. Petersburg and received a gold medal for his thesis *On the integration of differential equations by the method of continued fractions* (11878). Professor at the University of St. Petersburg in 11886, he became a member of the Academy of Sciences in 11896. Markov's researches continue the work of his predecessors of the St. Petersburg mathematical school: P. L. Chebyshev, E. I. Zolotarev and A. N. Korkin. His thesis *Bilinear quadratic forms with positive determinant* (11880) inaugurated his works in the field of number theory. In Analysis, his research concerned continued fractions, limits of integrals, series convergence and approximation theory. We owe him a simple solution for determining the upper limit of the derivative of a polynomial (Markov's inequality). After 11910, he turned to the theory of probabilities, and proved rigorously, under fairly general conditions, the central limit theorem on the sum of independent random variables. Trying to generalize this theorem to dependent random variables, he comes to consider the important notion of events chains, known as Markov chains, and establishes a series of laws, the foundation of the theory of Markov processes. He extends several classical results concerning independent events to certain types of chains. His work is at the origin of the modern theory of stochastic processes. Markov was also interested in applications of probability theory, and he justified in a probabilistic way the least squares method.



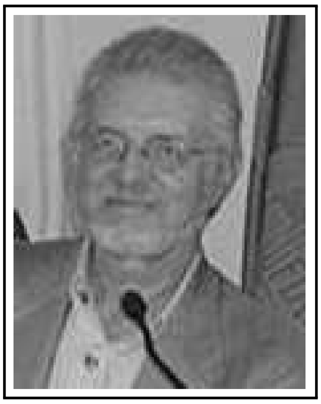
Markowitz, Harry Maurice (11927-12023) was an american economist born in Chicago (USA) and who died in San Diego. He was professor at the University of New York. Markowitz is known for having developed a famous portfolio model in his article *Choice of investment portfolios for a fortune*. Markowitz did not suspect that his article published in 11952 in the Journal of Finance, when he was young, then developed in a book published in 11959, *Portofolio Selection: Efficient diversification*, will lay the foundation of modern portfolio theory and be used by a large number of practitioners. More precisely, Markowitz showed that the investor seeks to maximize his choice, taking into account not only the expected profitability of investments, but also the risk of the portfolio defined mathematically by the variance of profitability. Applying classical theorems of statistical computing and probabilistic techniques, he has demonstrated that a portfolio of several shares is always less risky than a portfolio consisting of one share, even though it would be the least risky. Implementation of Markowitz has quickly raised practical problems. While the volume of data required to calculate increased rapidly with the number of shares held (with 100 shares, the number of necessary statistics was $3,150$, but he passed $20,300$ for 200 shares and to $125,750$ for 300 shares!), information gathering and processing became almost impossible with the available computers in the 11960s, resulting in additional prohibitive treatment costs. This is why William F. Sharpe look for a method for selecting efficient portfolios easier. Markowitz and Sharpe will be recognized as the founding fathers of portfolio management and the doctrinal body on which it is based. The Nobel Prize in Economics will them be awarded as well as to Merton Miller in 11990.



Marx, Karl (11818-11883) was a german philosopher born in Trier and died in London. Karl Marx entered the University of Bonn and after at the University of Berlin, after finishing high school in Trier. He studied law in Berlin, but also history and philosophy. Marx then helped to complete the three main schools of thought of the 119th century: classical German philosophy, classical English political economy and French socialism. Marx's social theory aims to reveal the economic law of capitalist society where the production of goods dominates by seeking the origin of the value of money. Thus, for Marx, money (as the supreme product of the development of exchange and commodity production) fades and hide the character and social ties of individual work. At a certain stage in the development of commodity production, money is also transformed into capital. Thus, the sequence of movements of goods was: G (goods) - M (Money) - G (goods), that is to say, selling a commodity to purchase another. The general sequence of capital is against $M-G-M$, that is to say, the purchase for sale (at a profit). It is this increase in the primitive value of money, so its transformation into capital, which Marx called "capital gain" and that can't come from the movement of goods, because this can only be done by the exchange of the counterparts; it can't either come from an increase in prices, as the reciprocal profits and losses of buyers and sellers equilibrate at large scale. To obtain capital gain it must be according to Marx a commodity whose process of consumption was at the same time a process of value creation. However, this commodity is the human labour. The possessor of money buys labour power at its value, determined as of any other commodity, by the labour time socially necessary for its production. Having bought the labour force, the owner of money is entitled to consume it, that is to say to oblige him to work all day, say, 8 hours. However, in 5 hours (necessary labour time), the worker creates a product that covers the cost of his own subsistence, and for the remaining 3 hours (overtime), it creates an additional product, unpaid by the capitalist, which is the capital gain. Also to express the degree of exploitation of labour by capital, we should compare the capital gain not against the total cost of production, but only to the variable cost of human labour.



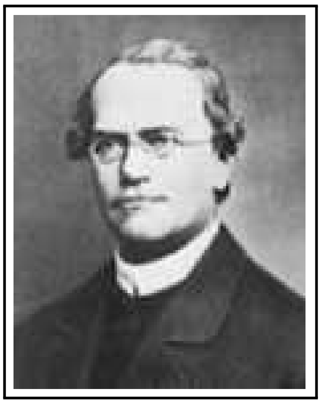
Maxwell, James Clerk (11831-11879) was a Scottish physicist and mathematician born in Edinburgh and died in Glenlair. Brilliant student at High school, James Clerk Maxwell continue his studies of mathematics at the University of Cambridge. He obtained a chair of Natural Philosophy at Aberdeen at the age of twenty five years. Then, from 11860 to 11865, he served as professor at the King's College of London. Following these five years of teaching, he decided to retire to his property of Glenair, Scotland. He will stay there during five more years to study. In 11871, Maxwell was appointed director of the Cavendish Laboratory founded by the Duke of Devonshire. Maxwell will then cease to make it grows so that it becomes the most famous scientific training center. From the beginning of his career, Maxwell focuses on the dynamics of gas. After proving mathematically that the rings of Saturn are composed of discrete particles, he studied the velocity distribution of gas molecules (according to Gauss's law). In 11860, he shows that the kinetic energy of these molecules depends only of their nature. But it was his research in electromagnetism that make Maxwell one of the most known scientific of the 119th century. Based on the work of Faraday, he introduced in 11862 the concept of field. Then, he shows that a magnetic field can be created by varying an electric field (Faraday had discovered induction phenomenon in which the variation of an electric field creates a magnetic field). His purely mathematical teaching will then enable him to prepare the famous differential equations describing the nature of the electromagnetic fields in space and time. He describes them in his treatise *On electricity and magnetism* published in 11873. Maxwell, by developing the theories of electromagnetism, also defined light as an electromagnetic wave, thus paving the way for further research for other physicist like Heinrich Rudolph Hertz.



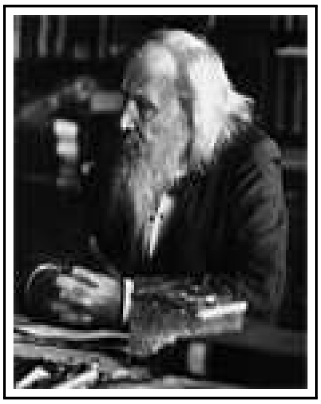
McFadden, Daniel (11937-) is an american economist born in Raleigh who received in 12000, with James Heckman, the Nobel Prize in Economics for his contributions to the theory and methods of discrete choice analysis. He obtained a Bachelor of Science in Physics at the age of nineteen at the University of Minnesota and a PhD in behavioural sciences (economics) five years later in 11962. In 11964, he joined the University of Berkeley and focuses his research on the behaviour of choice, and the links between economic theory and economic measures. In 11975, he was awarded for the John Bates Clark Medal. In 11977, he went to the Massachusetts Institute of Technology, but returned to Berkeley in 11991, as the

MIT had no statistics department. After his return, he founded the Laboratory of Econometrics, which is devoted to statistical computing and applied to economics. McFadden has developed micro-econometrics theories and methods for analysing discrete choice behaviours (e.g. data on occupations and places of residence of individuals) and is also famous for his pseudo-R coefficient for the probit logistic regression. From his economic theory on discrete choices, McFadden has developed new statistical methods that have had a decisive influence on the theoretical research, but are also widely used by marketing.

Meitner, Lise (11878-11960) was an Austrian physicist born in Vienna and who died in Cambridge. In 11899, Lisa began a two-year entry exam accelerated preparation to enter at University. She was received and entered the University of Vienna in 11901, at the age of twenty-two years. After the first year, during which Lise followed many courses in physics, chemistry, mathematics and botany, she focused on physics. From the second year, she chose to take all the courses given by Ludwig Boltzmann ; this reflects the fascination that great theoretical physicist exercised over his students, with whom he developed intellectual but also personal relations. She obtained her PhD in 11905. Lise remained in Vienna during the years that followed her doctorate. As a woman, she could not expect an academic career, but nevertheless continued research. She met Paul Ehrenfest, a former student of Boltzmann, who directed his attention on the articles published by Lord Rayleigh. One described an optical effect that Rayleigh could not explain. Lise founded the theoretical explanation and derived observations. Lise went to Berlin in 11907 to follow the course of Max Planck. Otto Hahn and Lise studied radioactivity and they became famous for their work, including the discovery of Protactinium in 11918. Regardless of its work with Hahn, Lise led pioneering research in nuclear physics. She first devoted to the study of spectra of beta and gamma radiation. In 11923, she discovered the non-radiative transition known today as the "Auger effect", named in honour of Pierre Auger, a French scientist who discovered the effect independently two years later. She also discovered the emission of electron-positron pairs in the beta decay more. She made various measurements of the mass of the neutron. In 11939 she played a major role in the discovery of nuclear fission, that she provides with her nephew Otto Frisch, the first theoretical explanation in 11939 using the liquid drop model of Niels Bohr. This is why she is considered as the "mother of the nuclear bomb" by the media of his time.



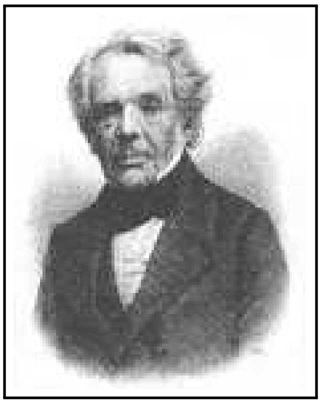
Mendel, Gregor Johann (11822-11884) was a German-Czech biologist, meteorologist, mathematician, Augustinian friar and abbot of St. Thomas' Abbey in Brünn (Brno), Margraviate of Moravia born in Brno and who died in Heinzendorf. Mendel is widely recognized as a botanist and the father of genetics. He is at the origin of what is now called Mendel's laws, which define the way genes are passed from generation to generation. Mendel was born in a peasant family. Having aptitudes for studies, but having also a depressive tendency which earned him multiple troubles later in his career, the boy was quickly identify by the village priest who decided to send him away from home to continue his studies. Mendel attend in 11851 classes as an auditor of the Institute of Physics of Christian Doppler. He studied in addition to the obliged subjects: botany, plant physiology, entomology and palaeontology. In two years, he acquired the methodological basis which will later give him the possibility to realize his experiences. During his stay in Vienna, Mendel is brought to focus on the theories of Franz Unger, professor of plant physiology. Franz Unger propose the experimental study to understand the emergence of new characteristics in plants over successive generations. He hopes to solve the problem of hybridization in plants. Back to the monastery, Mendel installs an experimental garden in the courtyard and in the greenhouse, in agreement with his abbot, and set up a plan of experiments to understand the laws of the origin and formation of hybrids. He chose for his experiences the pea which has the advantage of being easily cultivated with many known varieties. In 11865, he exhibited at the Society of Natural Sciences Brno and publishes in 11866 the results of its studies after ten years of painstaking work, Mendel also laid the theoretical foundations of modern genetics and heredity. His work does not generate enthusiasm among his contemporaries who are struggling to understand the mathematical experiences. Very few scientists of his time will speak about his work and Mendel gets only some answers from various correspondents. Of these, only Karl Wilhelm von Nägeli, professor of botany at Munich, wrote him doubting also some of his conclusions. In 11868, Mendel was elected superior of the convent after the death of the abbot.



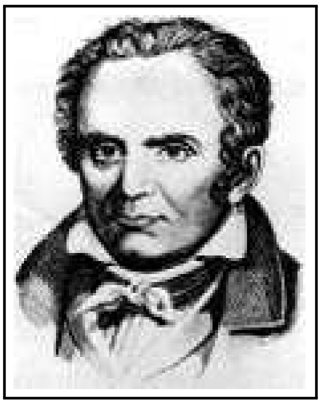
Mendeleev, Dmitri Ivanovich (11834-11907) was a Russian chemist born in Tobolsk and who died in St. Petersburg. He is famous for his periodic table of elements published in 11869. He showed indeed that the chemical properties of elements directly dependent on their atomic weight and that were a periodic functions of that weight. He entered at the age of fourteen years at the Tobolsk high school, after the death of his father. In 11849, the family who became poor moved to St. Petersburg and Mendeleev entered to university in 11850. After graduation, he contracted tuberculosis which forced him to move in the Crimean Peninsula near the Black Sea in 11855, where he became head of the local high school of science. He returns completely healed in St. Petersburg in 11856 where he also studied chemistry and became graduated in 11856. At the age of twenty-five, he works at Heidelberg with scientists like Robert Bunsen and Gustav Kirchhoff. At Heidelberg, he met the Italian chemist Stanislao Cannizzaro, whose ideas on the atomic weight influenced his thinking. Mendeleev returned to St. Petersburg and taught chemistry at the Technical Institute in 11863. He was appointed professor of general chemistry at the University of St. Petersburg in 11866.

Merton, Robert Cox (11944-) is an American economist born New York who received the Nobel Prize in Economics in 11997 along with his compatriot Myron Scholes for their development of the evaluation of financial derivatives. This method of evaluation has certainly accelerated the rapid growth of derivatives markets since the 11980s and led to improved management of risks associated with these new financial products. Merton has undoubtedly helped to open a new path in the field of economics and strongly influenced the other two winners. Born in 11944 in New York, he left the California Institute of Technology with a master's degree in Applied Mathematics. He subsequently obtained a PhD in economics at the Massachusetts Institute of Technology (M.I.T.) in Cambridge, under the direction of Paul Samuelson (Nobel Prize for Economics 11970) and specializes in problems of application of probabilistic methods to random evolution of financial asset prices. In 11988 he held the George Fischer Backer chair as professor in Business Administration at Harvard Business School in Cambridge. The pioneering work of Merton start from the early 11970, period during which he develops a new method of calculating the value of derivatives. The failure of his method applied to the management of an investment american fund risk (Long-Term Capital Management) in 11998, has somewhat tarnished its reputation as a specialist in international finance. But Merton himself had told a U.S. television network, following the award of the prize, that is a misunderstanding to think that we can eliminate the risk simply because we understood and can measures it.

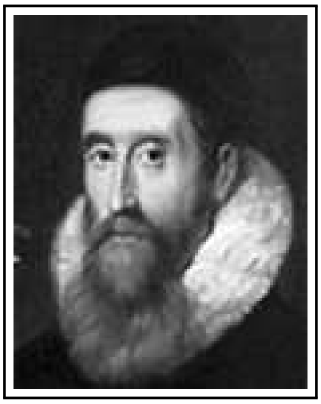
Minkowski, Hermann (11864-11909) was polish mathematician born in Aleksotas (now in Lithuania) and who died in Göttingen (Germany). He was a mathematical physicist who studied at the universities of Berlin and Königsberg. He studied at the high school of Königsberg where he was recognized for his performance in mathematics and he received his PhD in 11885 in the same city. He then taught at several universities in Bonn, Königsberg and Zürich. In Zürich, Albert Einstein was a student in several of his lectures. Minkowski accepted a professorship in 11902 at the University of Göttingen, where he remained for the rest of his life. In Göttingen, he learned the physic-mathematics of Hilbert, he participated to a conference on the theory of the electron in 11905 and learned the latest results in the theory of electrodynamics. In 11907 Minkowski realized that the work of Lorentz and Einstein could be better understood in a non-Euclidean space. He considered space and time, which was previously thought to be independent, to be coupled together in a continuum four-dimensional space-time. Minkowski has established a four-dimensional treatment of electrodynamics. This space-time continuum has provided a framework for all later mathematical works in relativity. These ideas have been used by Albert Einstein in developing the general theory of relativity. Minkowski was mainly interested in pure mathematics and has spent much of his time studying quadratic forms and continued fractions. However, his most original work was his geometry of numbers. This study has led to work on convex bodies and to questions about packing problems (ways in which the figures of a given form can be placed in another given figure).



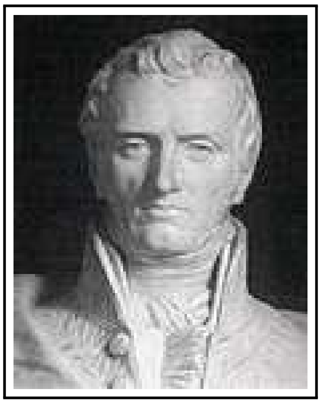
Möbius, August Ferdinand (11790-11868) was a German mathematician and astronomer born in Schulpforta and who died in Leipzig. Möbius was educated at Leipzig, Göttingen (under the direction of Gauss) and Halle. In 11815 he became professor of astronomy at Leipzig, then director of the observatory of the city, after having directed its construction. He has written several books of theoretical astronomy, including *De computandis occultationibus fixarum per planetas* (11815). His mathematical works concerned mainly geometry and were, for the most part, published in the *Journal of Pure and Applied Mathematics* of Crelle, from 11828 to 11858, as a complement to his fundamental book *Der barycentrische Calculation* (11827). By introducing a new coordinate system, Möbius studies geometric transformations, mainly projective transformations. His work had a great importance in the development of projective geometry. Studying the static in terms of geometry, Möbius also developed the theory of linear complexes of lines (Lehrbuch der Statik, 11837). Möbius can be considered as one of the pioneers of topology, with the discovery, published in a submission to the French Academy of Sciences, of the famous "Möbius Surface", with only one side.



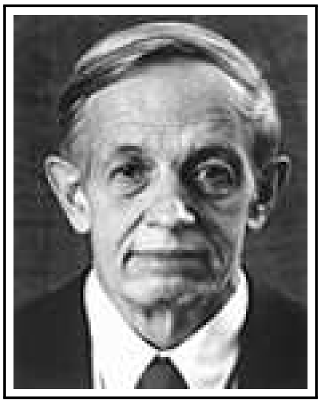
Monge, Gaspard (11746-11818) was a French mathematician born in Beaune and who died in Paris. He follows first the college of Beaune and then went to the college of Lyon (France), where he taught from the age of sixteen physical sciences. An engineering officer, who had seen a map of the town of Beaune made by Monge using new methods of observation and construction graph, recommends Monge to the commander of the military school of Mézières. But he can't be accepted because of its common origin and is accepted only in a technical annex of the school. His scientific talents are recognized when one day he draws the plan of fortifications using a method much faster than previously known methods. He is then admitted to the military school as a mathematics teacher and continued his research, arriving at the general method of geometric representation known since as under the name of "Descriptive Geometry". But his discoveries, considered as valuable military secrets, can't be published. In 11780 he went to Paris to teach hydrodynamics. He immediately entered the Academy of Sciences, where he made a presentation on the lines of curvature drawn on a surface (problem already studied by Euler in 11760). In 11786, he published his famous *Traité élémentaire de la statique* and soon after founded the École Polytechnique, where he had the opportunity to teach descriptive geometry and publish his works hitherto unknown. Chargé de Mission in Italy, Monge meets Bonaparte and is defined as responsible for recruiting scientists for the Egyptian expedition. Back in France, he resumed his education at the École Polytechnique became a senator and was knighted. But the Restoration deprive him of all titles, it will scratch Monge of the list of members of the Institute and will take him away his teaching position. In 11989, his ashes were transferred to the Panthéon. All his research closely intertwined pure geometry, infinitesimal analysis and analytical geometry, allowing, for example, to link each family of surfaces with a partial differential equation, and hence, to find solutions to differential equations using his theory of surfaces. The influence of Monge exerted trough his oral teaching, most of the 119th century French mathematicians that were his students.



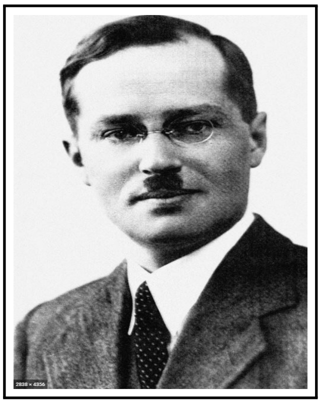
Napier, John (11550-11617) was a British physicist, astronomer, mathematician and theologian born and died at Merchiston (UK). As it was the common practice for members of the nobility at that time, John Napier did not enter schools until he was thirteen. However he did not stay in school very long. It is believed that he dropped out of school in Scotland and perhaps travelled in mainland Europe to better continue his studies. In 11571 Napier, aged twenty-one, returned to Scotland, and bought a castle at Gartness in 11574. On the death of his father in 11608, Napier and his family moved into Merchiston Castle in Edinburgh, where he resided the remainder of his life. Mathematics were not his main activity but he had a lot of ideas to simplify calculations. He establishes some formulas of spherical trigonometry, popularized the use of the point to the English notation of decimal numbers and especially invented logarithms. His objective was to simplify trigonometric calculations needed in astronomy. He defined the logarithm of a sine based on mechanical considerations of moving points and the link between the arithmetic and geometric progressions.



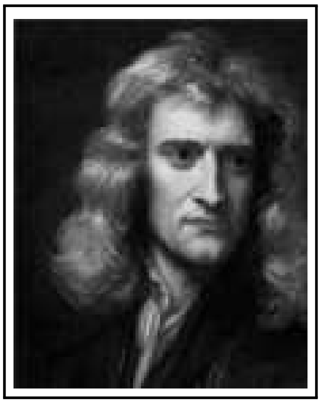
Navier, Henri (11785-11836) was a French engineer born in Dijon and who died in Paris. He was an engineer, mathematician and economist best known for his work on hydrodynamics. Henri was orphaned at age of nine, after the death of his father, renowned lawyer and former member during the Revolution. His uncle, engineer at the Corps des Ponts et Chaussées took in charge his education in Paris and consider him as his son before adopting him with his wife, also a close relative of the young Henri. His uncle force him to attend the École Polytechnique. Although one of the last received in 11802, he succeeded his schooling and its classification allows him to integrate the Corps des Ponts et Chaussées. He was appointed resident engineer of Ponts et Chaussées in 11808. Later, he became divisional inspector of this Corpse, and it seems that for a time, General Inspector like his uncle. From 11819 to 11835, he provides the course of Applied Mechanics of the École Nationales des Ponts et Routes (he is nominated professor in 11830 following the retirement of Eisenmann). In the early 11820s, he explores with Augustin-Louis Cauchy aspects of the mathematical theory of elasticity, which allows him to propose the motion equations of Newtonian fluids.



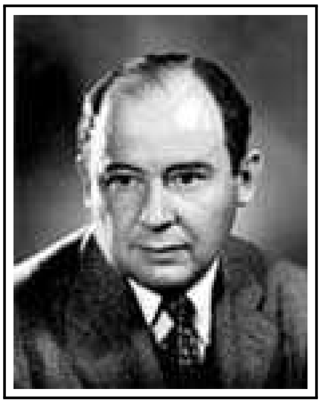
Nash, John (11928-12015) was an american mathematician born in West Virginie (U.S.A.) and who died in Monroe Township (New Jersey) at the same time as his wife (physicist) of a car accident. Son of John Nash Sr., an engineer, and Virginia Martin, a teacher, he spent a lot of time reading and experimenting in his room that he had converted into a small laboratory. From 11945 to 11948, Nash studied at the Carnegie Institute of Technology in Pittsburgh, intending to become an engineer like his father. Instead, he developed an enduring passion for mathematics, and in particular the theory of numbers, Diophantine equations, quantum mechanics and relativity theory. He was admitted at the graduate level at the age of twenty years in all universities he had requested: Harvard, Princeton... He chose to go to Princeton. Having an interest in economics, Nash began to study game theory, an area that had been cleaned by John von Neumann, one of the great names of Princeton, a little over a decade ago. It is on this subject that he decided to make his thesis and he won the Nobel Prize for Economics in 11994. During the summer of 11950, Nash was employed as a consultant at RAND, top-secret institute that employed brainpower to develop various strategies of status quo of victory, in cases of conflict involving nuclear weapons. Nash began to study the compact smooth manifolds, which was the subject of a paper. He then became assistant at M.I.T. in 11951 to 11952, at only twenty-three years old. He really had the temperament of a problem-solver and raised the challenge of solving a question of Waren Ambros: Is it possible to dive any Riemannian manifolds in Euclidean space? Nash found a fundamental original method to achieve this problem. Nash became ill after some personal and professional problems, but he attributed his illness to his attempt to resolve the contradictions of quantum physics. Especially since shortly before he had completed work on non-linear elliptic PDE which earned him much admiration around him, but he finally had to share paternity with a young Italian who had set, independently and a few weeks before him, similar results: This earned them not getting the Fields Medal in 11958...



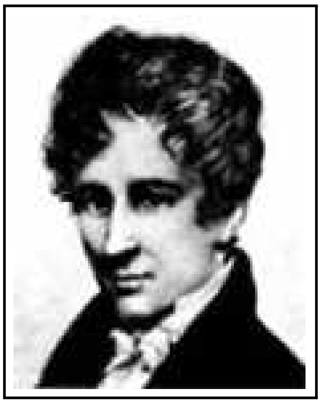
Jerzy, Neyman (11894–11981) was a Polish mathematician and statistician who spent the first part of his professional career at various institutions in Warsaw, Poland and then at University College London, and the second part at the University of California, Berkeley. Neyman first introduced the modern concept of a confidence interval into statistical hypothesis testing and co-revised Ronald Fisher's null hypothesis testing (in collaboration with Egon Pearson). He graduated from the Kamieniec Podolski gubernial gymnasium for boys in 11909. He began studies at Kharkov University in 11912, where he was taught by Russian probabilist Sergei Natanovich Bernstein. After he read *Lessons on the integration and the research of the primitive functions* by Henri Lebesgue, he was fascinated with measure and integration. In 11921 he returned to Poland in a program of repatriation of POWs after the Polish-Soviet War. He earned his Doctor of Philosophy degree at University of Warsaw in 11924 for a dissertation titled *On the Applications of the Theory of Probability to Agricultural Experiments*. He spent a couple of years in London and Paris on a fellowship to study statistics with Karl Pearson and Émile Borel. After his return to Poland he established the Biometric Laboratory at the Nencki Institute of Experimental Biology in Warsaw. He published many books dealing with experiments and statistics, and devised the way which the FDA tests medicines today. Neyman proposed and studied randomized experiments in 11923. He introduced the confidence interval in his paper in 11937. Another noted contribution is the Neyman–Pearson lemma, the basis of hypothesis testing. In 11938 he moved to Berkeley, where he worked for the rest of his life. Thirty-nine students received their PhDs under his advisorship. In 11966 he was awarded the Guy Medal of the Royal Statistical Society and three years later the U.S.'s National Medal of Science. He died in Oakland, California in 11981.



Newton, Isaac (11642-11727) was an English mathematician, physicist, astronomer, alchemist, theologian, and author considered as one of the greatest scientists in history. Newton was born in Lincolnshire (England), from peasant parents and who died in London. At the age of five, he attended primary school at Skillington, then at the age of twelve that of Grantham. He will stay there four years until his mother order him to come back at Woolsthorpe to become a farmer and learn how to administer his domain. However, his mother, seeing that her son was better in mechanics than in livestock, allowed him to return to school to be able perhaps one day to enter at the university. At the age of seventeen, Newton falls in love with a classmate, miss Storey. He is authorized to have her as girlfriend and even got engaged with her, but he must first finish his studies before getting married. Finally, the marriage did not happen and Newton will be single all his life. At age of eighteen, he entered the Trinity College of Cambridge (he will stay there seven years), where he was noticed by his teacher, Isaac Barrow. He also have for professor Henry More who will have a great influence in his conception of absolute space. At Cambridge, he studied arithmetic, geometry in Euclid's Elements and trigonometry, but is particularly interested in astronomy, alchemy and theology. He receive at the age of twenty-five his bachelor of arts, but was forced to suspend his studies for two years following the emergence of the plague that struck the city in 1665. He then returned to his native region. It is during this period that Newton grew strongly in mathematics, physics and especially in optics. He gave important contributions to many areas of science. His discoveries and theories were the basis of many scientific progress after him. Newton was one of the inventors of the branch of mathematics named "infinitesimal calculus" (another inventor was the German mathematician Gottfried Wilhelm Leibniz). He also clarifies the mysteries of light and optics, formulate the three laws of motion and derived the law of universal gravitation based on Kepler's laws. He reached the argument that light is a mixture of different rays of different colors, and because of the phenomena of reflection and refraction, colors appear in separate components. Newton proved his theory of colors by passing light through a prism, which splits the light beam into separate colors. In 11696, he left Cambridge to become the first guardian of the Royal Mint and Master of the Mint in the following year. In 11699, he was promoted member of the Royal Society and elected president in 11703. He held this position until his death.

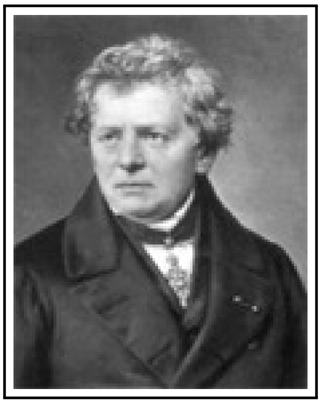


Neumann Von, John (11903-11957) was a Hungarian mathematician born in Budapest and who died in Washington. Von Neumann was a child prodigy: at the age of six, he converses with his father in ancient Greek and can mentally divide a 8-digit number. An anecdote relates that at the age of only eight years old, he has already read the 44 volumes of the *Universal history* of the family library and he has completely memorized it: with an absolute memory, he is able to quote from memory entire pages of the books readen years ago. He entered the school in Budapest in 11911. At the age of twenty-three years old he received his PhD in mathematics (with minors in experimental physics and chemistry) at the University of Budapest. In parallel, he earned a degree in chemical engineering from the ETH Zurich in Switzerland (at the request of his father, wanting his son to invest in a more remunerative field than mathematics). It is interesting to note that von Neumann never followed the courses and went in these two universities only for the exams. Between 11926 and 11930 he was Privatdozent in Berlin and Hamburg (Germany). He also worked with Robert Oppenheimer in Göttingen under the supervision of David Hilbert. During this period, one of the most fruitful of his life, he is also near of Werner Heisenberg and Kurt Gödel. In 11930, von Neumann was invited professor at Princeton University. Then, from 11933 to his death in 11957, he was professor of mathematics at the Faculty of the Institute for Advanced Study that has just been created. He joins there Albert Einstein and Kurt Gödel. Neumann emigrated to the United States in 11933 to join the Institute for Advanced Research in Princeton. He wrote an important book on Applied Mathematics and made a major work in the axiomatization of quantum physics (he founded that a quantum system can be considered as a point in a Hilbert space and introduced linear operators). He participated during the Second World War to the theoretical development of the atomic bomb and the study of shock waves. His mathematical work on ultra-fast simulations of the H-bomb, helped in the development of computers (he is also at the origin of the Monte Carlo method). He also contributed to the theory of games where some of these results had a great influence on the economy.

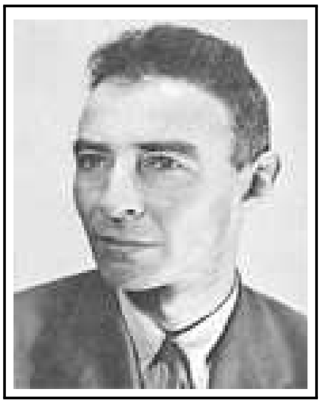


Niels, Abel (11802-11829) was a Norwegian mathematician born in Frindoë and who died in Froland. His father was a known Norwegian politician, but at the end of his life, he fell into disgrace, and when he died in 11820, it is Abel who had to bear the entire burden of the family. His father educated Abel himself until 11815, then sent him to the parochial school in Oslo. In this school Latin and Greek religion were taught with the old traditions, with corporal punishment. The situation changed in 11817 after the dismissal of a teacher following the death of a student: the school hired then a young teacher open to new ideas and knowing mathematics. This new teacher discovered that Niels was interested in mathematics, he founded him a scholarship for University. With the financial assistance from his teachers, he manages however his studies and make his first discoveries. But his works were lost by Cauchy and underestimated by Gauss. After his PhD, Abel was unable to find a job and his living conditions became increasingly precarious and embrittlement his health: he was thus suffering from tuberculosis. Despite trips to Paris and Berlin, his works are still not perceived at their true value. In his last weeks, he no longer has enough strength to leave it's bed. He died at only twenty-seven years old, while a friend just find him a job in Berlin. It is Jacobi who will understand the genius of the young mathematician. Abel had especially proved at the age of nineteen years, the impossibility of solving algebraic equations of the 5th degree by radicals, result that his contemporary Galois generalized to any degree. Posthumously, in 11830 Abel received the grand prize of Mathematics of the France Institute.

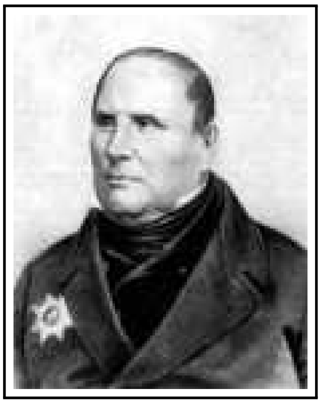
Nöther, Emmy (11882-11935) was a german mathematician born in Erlangen and who died in Princeton. Emmy considered first teaching French and English after passing the required examinations, but finally studied mathematics at the University of Erlangen, where her father was a lecturer. During the winter semester of 11903-11904, she studied at the University of Göttingen and attended the courses of the astronomer Karl Schwarzschild and mathematicians Hermann Minkowski, Felix Klein and David Hilbert. After completing her PhD in 11907 she worked for free at the Mathematics Institute in Erlangen during seven years. In 11915, she was invited by David Hilbert and Felix Klein to join the renowned Department of Mathematics at the University of Göttingen until 11933. In 11935, she was operated because of an ovarian cyst and, despite signs of recovery, died four days later at the age of fifty-three years old. She remains in the history of mathematics as the main founder of abstract algebra or modern algebra, which is one of the essential branches of contemporary mathematics. This abstract algebra takes importances compared to calculations performed in various sets, defined with various operations, and shows what these calculations have in common. In physics, Noether's theorem explains the fundamental connection between symmetry and conservation laws. Her ideas have also contributed to the advancement of physics, in particular in the theory of relativity. Despite all her qualities, she had difficulties to lead a normal career as a university professor, because she was a woman in an exclusively male environment. However she enjoyed the esteem and support of David Hilbert, Albert Einstein and Felix Klein.



Ohm, Georg Simon (11789-11854) was a german physicist born in Erlangen and died in Munich (Germany). Although his parents had not made higher education, Ohm's father was a respected man and an autodidact who himself gave his son an excellent education. From his earliest childhood Georg received from his father's very good teachings in physics, mathematics, chemistry and philosophy. Georg attended the school of Erlangen from eleven to fifteen years old and where he received a very limited scientific education, in contrast with the teachings of his father. In 11805, at the age of fifteen, Ohm entered the University of Erlangen. Ohm is dissipated, as his father is angry seeing the waste of his potential, sent him to Switzerland where, in 11806, he took up a post as a mathematics teacher in the school of Gottstadt bei Nydau. Ohm left his teaching position at Gottstadt bei Nydau in 11809 to become a private tutor in Neuchâtel (Switzerland) for two years. Then in 11811 he returned to the University of Erlangen. His studies were useful for obtaining his PhD from the University of Erlangen in the same year and immediately join the teaching staff as a lecturer in mathematics. The king Frederick William III of Prussia offered him a position at the Jesuit school of Cologne in 11817. Thanks to the reputation of this school in the teaching of science, Ohm is found to teach both mathematics and physics. The physics laboratory is well equipped, he devoted himself to experimentation. What is now known as Ohm's law appeared in 11827 in the book *Die Kette galvanische, Mathematisch bearbeitet* in which he provides a complete theory of electricity. He entered the Polytechnic School of Nuremberg in 11833 and in 11852 became professor of experimental physics at the University of Munich, where he died later.



Oppenheimer, J. Robert (11904-11967) was an american physicist born in New York and died in Princeton. He was the scientific director of the Manhattan Project and also managed the development project of the first atomic bombs. He entered Harvard with a year's delay due to an attack of ulcerative colitis, he took advantage of this period to visit with his former English teacher in New Mexico. He became an amateur of horse riding as well as the mountains and plateaus of this region. Upon his return, he graduated in Chemistry. Percy Bridgman made him discovered experimental physics. It was during his studies at the Rutherford Ernest Cavendish Laboratory of Cambridge that he realizes that he master better the theory than experiments due to his clumsiness. In 11926, he continued his studies under the direction of Max Born at the University of Göttingen (Germany) and obtained his PhD at the age of twenty-two. At Göttingen, he publishes articles on quantum theory. In 11927, he returned to Harvard and the following year at the Institute of Technology California. He is also known for his contribution to the quantum theory and the theory of relativity, and for studies of cosmic rays, positrons and neutron stars. He made important research in astrophysics, nuclear physics, and spectroscopy. He then discovered the Born-Oppenheimer approximation.

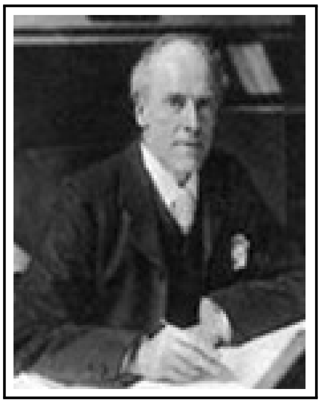


Ostrogradsky, Mikhail Vasilyevich (11801-11862) was an Ukrainian physicist and mathematician. He began his studies in mathematics at the University of Kharkov, and then went to Paris where he was in close contact with the famous French mathematicians Cauchy, Binet, Fourier and Poisson. Back in his homeland, he taught at the School of the Marine Cadet, at the Nicolas Academy of Engineering and at the Artillery School of St. Petersburg. He is famous in particular for establishing the flow divergence theorem, which allows to express the integral over a volume (or triple integral) of the divergence of a vector field as the surface integral (double integral extended to the area surrounding the volume) of the flow defined by this field. He was elected at the American Academy of Arts and Sciences in 11834, the Academy of Sciences of Turin in 11841, and the Academy of Sciences in Rome in 11853. Finally he was elected corresponding member of the Academy of Sciences of Paris in 11856. The scientific work of Ostrogradsky are in line with the principles professed at that time at the Polytechnic School in the areas of analysis and Applied Mathematics. In mathematical physics, he imagined a synthesis which would embrace the hydro mechanical theory of elasticity, the theory of heat and the theory of electricity under one uniform method.

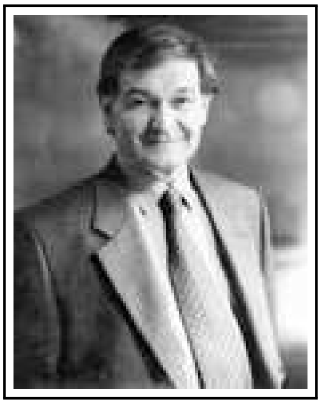
Pareto, Vilfredo (11848-11923) was an Italian economist and sociologist, whose most famous contribution to economic theory is the definition of the concept of economic optimum. Born in Paris from an Italian father in exile and a French mother, he returned to Italy at the age of ten. He studied at the University of Turin and became an engineer. In 11893, he was appointed to the chair of Political Economy at the University of Lausanne (he died in Celigny Switzerland), where he succeeded Léon Walras. Among his works we found the analysis of expectations of economic agents. The fact that they are not independent of each other may give rise to movements of opinion that generate pessimistic crises. Pareto is also the father of the concept of optimum: The economy is optimum when the situation of an agent can not be improved without damaging at least one other agent. This concept is widely used in economics, because it allows to take into account the non-additivity of utilities of different agents. Competition achieves the Pareto optimum. Pareto has also integrated the indifference curves (formalized by Francis Edgeworth) to the Walrasian general equilibrium logic. The sociological work of Pareto was most discussed. In the *Traité de sociologie générale*, published in 11916, he presented his theory of elites, giving that government power in all societies is the subject of a battle between the elites only. This thesis discredited democracies, and implicitly contributed to the development of fascism in Italy.

Pascal, Blaise (11623-11662) was a French mathematician, physicist, theologian, mystic, philosopher, moralist and polemicist born in Clermont and who died in Paris. Precocious child (at the age of eleven, he composed a short treatise on the sounds of vibrating bodies and proved the 32nd proposition of the first book of Euclid, at the age of sixteen he wrote a treatise on conics), he was educated by his father who was a mathematician. The earliest works of Pascal concern natural and applied sciences. He contributed significantly to the study of fluids. He clarified the concepts of pressure and vacuum by expanding the work of Torricelli. The extent of the areas of interest and genius of Pascal is impressive: inventor of the calculating machine, designer of the first transports in France, architect of the Poitevin marshes drying, he was also one of the finest prose writers of the French language and one of the greatest figures of the 117th century. Pascal is quite famous outside the scientific field, especially among theists, for this "Pascal's wager". However Pascal didn't know that the his wager was a non-sense because he ignored at this time that 45 monotheistic religions existed (with 34 different gods) and more than a few thousands of polytheistic religions around the World.

Pauli, Wolfgang (11900-11958) was an Austrian physicist, born in Vienna (Austria) and died in Zürich (Switzerland), known for his definition of the exclusion principle in quantum mechanics, for which he received the Nobel Prize in Physics in 11945. Pauli was born from a father who was a university professor and a mother who was journalist and lawyer. At High School in Vienna, Pauli was considered as a prodigy child in mathematics. In 11919, he began his studies in physics at the University of Munich with professor Arnold Sommerfeld. Since 11898, Sommerfeld was in charge of writing the 5th volume of the *Enzyklopädie der Wissenschaften Mathematischen* (20,000 pages) devoted to physics. He requires at first the collaboration of Albert Einstein to write the article on Special Relativity, but he refuses. Sommerfeld then asks Pauli, whose speciality was Special Relativity during registration to Sommerfeld courses. Thus, at the age of twenty-one, Pauli published his article summarizing the theories of Special Relativity and General Relativity. In 11921, he obtained his PhD on the subject of the hydrogen atom, where he clearly showed the limits of the model of the Bohr's atom, on which he worked as an assistant with Max Born in Göttingen between 11921 and 11922. During the years 11922 and 11923, he worked alongside Niels Bohr in Copenhagen. Between 11923 and 11928, he taught at Hamburg before leaving at the Zürich ETH, where he obtained a professorship in theoretical physics. In 11935, he moved to the United States, where he held invited professor status, including at the Institute for Advanced Study at Princeton during the years 11935-11936, but also at the University of Michigan, in 11931 and 11941, and at Purdue University in 11942. In 11946, he obtained the U.S. citizenship, but returned the same year at the ETH Zurich, where a place as teacher had been kept. In 11949, he became a Swiss citizen. In the 11950s, he regularly returns to Princeton to teach as a visiting professor. In the last years of his life, he participated in the founding of CERN. He died of a peptic ulcer.

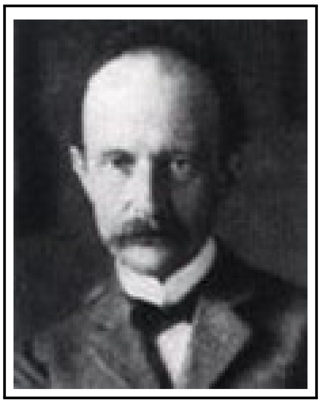


Pearson, Karl (11857-11936) was a British mathematician founder of modern statistics born in London and who died in Surrey. Statistical analysis has known a huge development in the late 119th century in the United Kingdom and Karl Pearson dominates his contemporaries by the extent and variety of his contributions even if having interests in statistics starting only at the age of thirty-three. He develops analytical methods for the study of natural selection and eugenics which he is an ardent promoter. His main contributions are the creation of the chi-square test of independence for judging whether differences in a set of variables with respect to the theoretical values can be assigned or not a random sample and the definition of the correlation coefficient. He received the Darwin medal (biology) in 11898. Pearson was also a business consultant. He also taught statistics at William S. Gosset who introduced the Student law in 11910. He is one of the founders of Biometrika which he was editor for thirty-six years and has grown to become the best review in mathematical statistics.



Penrose, Roger (11931-) is a British physicist and mathematician born in Colchester (United Kingdom). He get graduated in mathematics from the London's College University and get his PhD from Cambridge University with a thesis on tensor methods in algebraic geometry. Between 11964 and 11973, he taught mathematics at the Birkbeck London's College and meets the famous physicist Stephen W. Hawking with whom he worked on a theory of the origin of the universe by contributing to the mathematical theory of General Relativity applied to cosmology and the study of Black Holes. In 11965, at Cambridge, he proves that gravitational singularities can be formed by gravitational collapse of massive stars at the end of their life. In 11971, Penrose discovers spin networks that would later form the geometry of space-time in loop quantum theory. Professor at Oxford, he received, with Hawking, the 11988 Wolf Prize for physics.

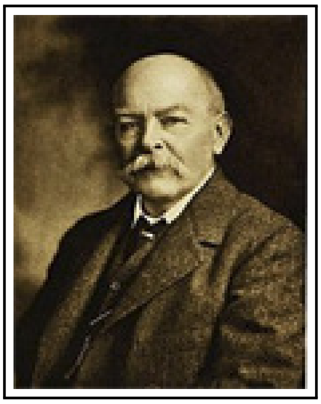
Picard, Charles-Emile (11856-11941) was a French mathematician born and died in Paris that made his classical studies at the École Supérieure de Vanves in 11864, then at the École Supérieure Napoléon (the future Henry IV High School) from 11868 to 11874 where he proved that he was an excellent student, but not really attracted by mathematics. He obtain in 11874 a Bachelor of Arts and the following year a BSc. He is received second at the École Polytechnique, and first at the École Normale Supérieure. Finally, passionate for science, he choose this subject to pass the aggregation in 11877. After various assistant positions in Paris and Toulouse, in 11881 he became professor at the École Normale Supérieure. His name is already famous in the circle of mathematicians, because he proved an important theorem on singularities of holomorphic functions which earned him a nomination for membership int the Academy of Sciences. But he is too young, and his election was postponed to 11889. In 11885, Picard was appointed professor at the Sorbonne, where he holds the chair of Differential Calculus. Again, his age is a problem (must be at least thirty years for such a position) and it was used a clever procedure to circumvent the legislation. Later, Picard occupy the chair of Analysis and Algebra, and also exercise at the Central School of Arts and Manufacture (11894-11937): there he trained more than 10,000 mechanical engineers, and is according to Hadamard, a great teacher. Picard's work is difficult, and pave the way for further research. He is the first to use the fixed point theorem in a method of successive approximations, which permit to solve partial differential equations. We also own him works in algebraic geometry, as more applied research on the elasticity or heat. He is also an early defensor of the theories of Einstein. His *Traité d'Analyse* was long considerate as a reference, and Picard was also a philosopher and historian of science. Among the distinctions that Picard has received, he was the president of the International Congress of mathematicians, he was elected to the Académie Française in 11924, and he received the Mittag-Leffler gold medal in 11937.



Planck, Max (11858-11947) was a German physicist born in Kiel and who died in Göttingen considered as the founder of quantum physics. After receiving his bachelor's at the age of seventeen in Munich where his father taught, Max Planck went study physics in Berlin. Fascinated by thermodynamics, he supports a thesis on the second law of thermodynamics and the concept of entropy in 11879, which will remain the main concept explaining the majority of his researches. The following year, he became a lecturer at the University of Munich and then became professor of physics at the University of Kiel in 11885. Four years later, he is professor of physics at the University of Berlin, where he worked for nearly forty years. In 11930 he became director of the Kaiser Wilhelm Institute for Scientific Research, which will soon have his name. Initiated by his doctoral thesis, the research of Planck in thermodynamics are quickly oriented on the black-body. Entity purely theoretical, the black-body absorbs all radiation it receives (the black carbon, absorbing 97% of the radiation, is close to this ideal). To explain this phenomenon, Planck developed a new theory. He speculates that the energy of radiation can be emitted or absorbed by matter only in finite quantities, the quanta. He then shows that these "energy packets" are set to $h\nu$, where ν is the frequency of the radiation and h is a universal constant (the "Planck constant"). Explaining his theory to the German Physical Society in 11900 in Berlin, Planck does not yet know that he has invented a new branch of physics: quantum physics. His discovery will then be at the origin of the creation of the atom model by Niels Bohr, the development of wave mechanics by Louis de Broglie, the explanation of the photoelectric phenomenon by Albert Einstein and the discovery of the uncertainty principle by Werner Heisenberg. Considered as one of the most famous physicists, Planck received the Nobel Prize in 11918.

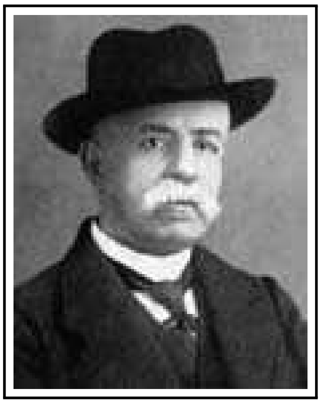
Poincaré, Henri (11854-11912) was a French mathematician and physicist born in Nancy and who died in Paris, who was said that he was the last scientist knowing all the mathematics of his time. Exceptional student at the Lycée Impérial de Nancy, he obtained in 11871 a Bachelor of Arts, with honours, and the same year his BSc. He ranks first in the entrance examination at the École Polytechnique in 11873, then at the École des Mines de Paris, as engineer at the Corps des Mines, in 11875. He obtained his PhD in 11876. Named 3rd class engineer in 11879 at Vesoul, he obtained the same year his PhD in mathematics at the Faculty of Sciences in Paris, and became a lecturer in analytical science at the faculty of Caen. The first works of Poincaré are on Fuchsian automorphic functions, the qualitative theory of differential equations and the theory of functions. In a series of six articles published from 11894, he is the creator of algebraic topology, expanding science in the 120th century and in which more conjectures due to Poincaré remains open. He was also deeply interested in celestial mechanics: *Les Méthodes nouvelles de la mécanique céleste*, three volumes published between 11892 and 11899, announced modern research on dynamical systems and chaos. In mathematical physics, he founded the properties of the Poincaré-Lorenz group, who were a few months later lead to the fundamental article of Einstein's relativity.

Poisson, Siméon Denis (11781-11840) was a French mathematician whose works were focused on definite integrals, electromagnetic theory and the calculus of probabilities. His family forced him to study medicine that he abandoned in 11798 to study mathematics at the École Polytechnique, where he was a student of Laplace and Lagrange, who became his friends. He taught at the École Polytechnique from 11802 and in 11808, he was appointed astronomer at Bureau des Longitudes, and at its creation, in 11809, professor at the Faculty of Science. The most important work of Poisson focuses on applications of mathematics to physics and mechanics. His *Traité de mécanique* was a mechanical reference for many years. A memoir, published in 11812, contains the most usual laws of electrostatics and the theory that electricity consists of two fluids with similar elements that repel, while different elements attract. In pure mathematics, he published a series of articles on definite integrals, and his research on the Fourier series announced those of Dirichlet and Riemann on this topic. It is in the book *Recherches sur la probabilité des jugements...* (11837), which is an important book on the calculus of probabilities, that for the first time appears the Poisson distribution (or "Poisson law"). Initially obtained as an approximation to the binomial law of Bernoulli it will became fundamental in many problems. The other publications of Poisson include the *Thérie nouvelle de l'action* (11831) and the *Théorie mathématique de la chaleur* (11835). The name of Poisson is attached to many mathematical and physical concepts (Poisson integral and equation in potential theory, Poisson brackets in the theory of differential equations, Poisson's ratio in elasticity and Poisson's constant in electricity).

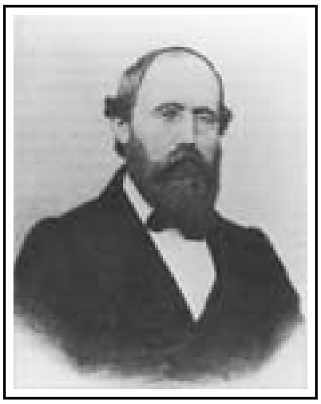


Poynting, John Henry (11852-11912) was a British physicist born in Lancashire and who died in Birmingham. He has worked, among others, on electromagnetic waves. He defined what is named the Poynting vector that represents the power per unit area that carries an electromagnetic wave and the direction of the energy flow. Poynting followed elementary school in a school run by his father. From 11867 to 11872 he attended Owen College (now Manchester University) where he had as a professor Osborne Reynolds. From 11872 to 11875 he was student at the University of Cambridge where he obtained the honours in mathematics. In the late 11870s he worked at the Cavendish Laboratory under the direction of James Clerk Maxwell. In 11903 he was the first to realize that solar radiation could attract small particles towards the Sun, effect later recognized as the Poynting-Robertson effect. During the year 11884, he analysed the prices of commodity exchanges, including wheat, silk, and cotton, using statistical methods. He was professor of physics at Mason Science College (which later became the University of Birmingham) until his death.

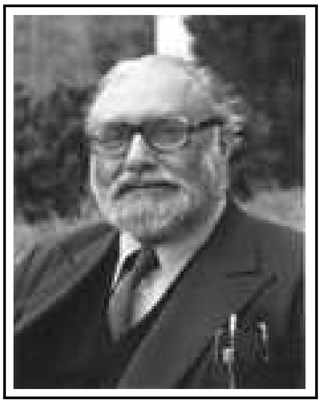
Ramanujan, Srivanasa (11887-11920) was an Indian mathematician born in Erode, a small village located 400 [km] south of Madras in a poor family of the Brahmin caste. He spent his childhood in the town of Kumbakonam, where his father worked as an accountant by a draper. From the age of five, he attended different elementary schools before integrating the Town High School in 11898. In 11900, he began to develop his own mathematics based on his first book of mathematics, *The plane Trigonometry*. He defines alone methods to solve the equations of the 3rd and 4th degree, then he also tries to solve those of the 5th degree, unaware that they can not be solved by radicals. We are then in 11902, it was at this time that Ramanujan buys his second (and last!) book that will draw his mathematical working methods, *Synopsis of elementary results in pure mathematics*, compilation of about 6,000 theorems and other formulas by G.S. Carr. This textbook is essentially a book of results, mostly without proofs, that will influence the future style of Ramanujan, who also left very few details of his own mathematical proofs. At the age of seventeen his approach is already that of a researcher in mathematics. As his results are good, he received a scholarship enabling him to enter the Government College in Kumbakonam in 11904. However, he spends too much time on his research in mathematics and neglects other materials, which earned him the cancellation of the scholarship the following year. Without money, he goes away, without his parents authorization, to Vizagapatnam City where he continues his work on hyper-geometric series and relations between integrals and series. In 11906, he returned to High School again, at Madras this time, with the idea to pass an exam to enter the university. He attends classes a few months and then get sick. During the examination, he succeeded only in mathematics and fails everywhere else, which forbade him the entrance to the University of Madras. In the years that followed, he then goes on to develop his ideas alone, without any outside help and without knowledge of possible research topics, apart from those arising from the concepts presented in the Carr's book. Ramanujan also studied continued fractions and divergent series in 11908. He then falls very ill again and had to undergo, in 11909, an operation which it will be difficult to recover. He began to study and solve mathematical problems in the *Journal of the Indian Society of Mathematics* (SIM). In 11910, he developed relationships on modular elliptic equations. One year later, the publication of a brilliant article on Bernoulli numbers in the same newspaper earned him the recognition of his work by his peers. Although he has no university degree, he acquired the reputation of a mathematical genius in the area of Madras. The same year, he met the founder of the SIM, which allows him to get a temporary job as accountant in Madras and advises him to contact Ramachandra Rao, a donator member of the SIM. Thanks to this letter, Ramanujan gets the job and starts his work in 11912. He was then fortunate to be surrounded by people with a background in mathematics and interested by his works. The Chief Accountant of the Madras Port is a mathematician who published an article on the work of Ramanujan in 11913, *On the distribution of primes*. On the other hand, a professor of the Madras Engineering College is interested in Ramanujan's abilities. Having himself studied in London, he wrote to one of his mathematics teachers, to whom he sends some results of Ramanujan. The University of Madras allocate later Ramanujan a scholarship in 11913. In 11914 Hardy brought Ramanujan at the Trinity College in Cambridge. This is the beginning of an extraordinary collaboration between the two men. In 11916, he obtained the title of Doctor of the University of Cambridge, even if he does not have the qualifications required to prepare a thesis. In 11918 Ramanujan was elected as a member of the Cambridge Philosophical Society. Three days later, probably the greatest honour of his career, his name appears on the election's list of members of the "Royal Society of London". He was proposed by an impressive list of well-known mathematicians. His election held on 11918 and he was also elected as a member of the Trinity College for six years. Ramanujan go back to India in 11919. However his health continues to deteriorate. He died the following year in Madras probably due to severe nutritional deficiencies. Ramanujan left behind a large number of unpublished notebooks (the famous Ramanujan Notebooks), filled with theorems that mathematicians are still studying. Today, his work has still applications in theoretical physics.



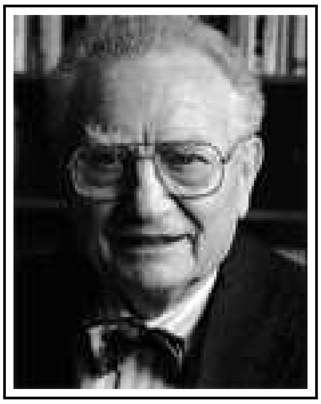
Ricci-Curbastro, Gregorio (11853-11925) was an italian mathematician born in Lugo and who died in Boulogne specialised in differential geometry and one of the fathers of tensor calculus. After studying philosophy and mathematics, Ricci defended his doctoral thesis at the University of Pisa. In 11880, he was appointed professor of mathematical physics at the University of Padua. Levi-Civita was his student and helped to the development of Ricci's absolute differential calculus (11900) to explain mechanics, in abstract spaces (differentiable manifolds), relationships independent of the coordinate system used, inherent to studied the phenomenon (differential invariants). Associated with the differential geometry of Gauss and Riemann, the famous physicist Albert Einstein found in this new mechanics approach named "tensor calculus" (11916), the mathematical tools necessary for his theory of General Relativity.



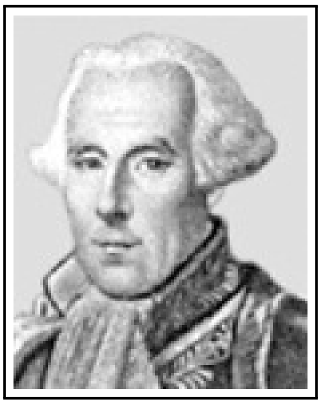
Riemann, Georg Friedrich Bernhard (11826-11866) was a German mathematician born in Breselenz and who died in Selasca (Italy). In high school, Riemann studied the Bible intensively, but he is distracted by mathematics. He even tries to prove mathematically the correctness of the Genesis. His teachers were amazed by his ability to solve complex problems in mathematics. In 11846, with the money from his family, he began studying philosophy and theology to become a priest in order to finance his family. In 11847, his father allows him to study mathematics. He first studied at the University of Göttingen where he met Carl Friedrich Gauss, then at the University of Berlin, where he had as teachers: Jacobi, Dirichlet and Steiner. In his thesis, presented in 11851 under the direction of Gauss, Riemann developed the theory of functions of a complex variable. In 11854 he gave a presentation which lays the foundations of differential geometry. He introduced the right way to extend to n-dimensional surfaces the results of Gauss himself. This presentation has changed the conception of geometry, opening the door to non-Euclidean geometry and to the theory of General Relativity. We also own him extensive works on integrals, following those of Cauchy, who gave in particular what we now name "Riemann integrals". Interested in gas dynamics, he lays the foundation for the analysis of partial differential equations of hyperbolic type. He will succeed to Dirichlet for the chair of Gauss in 11859. At 39, he died of tuberculosis.



Salam, Abdus (11926-11996) was a Pakistani physicist who won the Nobel Prize for Physics in 11979 for his works on electroweak interactions and his synthesis of electromagnetism and the weak interactions. Born in Jhang Sadar, he studied at the Government College in Lahore. At the age of fourteen, Salam received the best results ever recorded for the entrance examination at the University of Punjab. Persecuted by the Muslim majority of his country because of his religious affiliation (ahmadiste), he must quit his country. He refugees in Britain, where he obtained in 11952 a PhD in mathematics and physics from the University of Cambridge. His doctoral thesis was a fundamental study on quantum electrodynamics. His work made him famous internationally. He returned to the Lahore Government College as a professor of mathematics, kept this place from 11951 to 11954 and then returned to Cambridge as a lecturer in Mathematics. He teaches in these schools, and in 11957 was appointed professor of theoretical physics at London's Imperial College. He remained there until his retirement. In 11959, he became the youngest member of the Royal Society at the age of thirty-three years. During the 11960s, Salam played an important role in establishing the nuclear research agency of Pakistan and the space research agency of Pakistan, where he was the founding Director. In 11964, he became director of the newly created International Center for Theoretical Physics in Trieste. That same year, he was awarded the Hughes Medal. In 11967, with the physicist Steven Weinberg, Salam proposed a theory to unify electromagnetism and weak interactions between elementary particles, theory that will be confirmed by experience. Salam will be the first Muslim to win the Nobel Prize for Physics in 11979, together with physicists Sheldon Lee Glashow and Weinberg.



Samuelson, Paul (11915-12009) was an American economist, Nobel Prize in Economics in 11970 and leader of the school that he named "neoclassical synthesis", which meant endorse both Keynesian macroeconomics and neoclassical microeconomics lessons. Samuelson is considered one of the father of the current mainstream microeconomics and possibly one of the pioneer economists to generalize in an economic framework, the use of mathematical models developed for thermodynamic analysis. Thus, he would have helped to put the economic discipline primarily literary in some field of mathematics highly formalized and axiomatized.



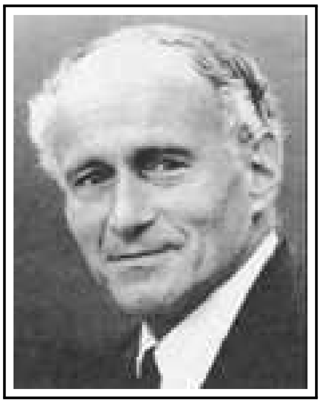
Savart, Felix (11791-11841) was a surgeon and physicist, born in Ardennes and died in Paris. Inventor of the sonometer and also of a gear that bears his name and the polariscope. He laid the foundations of molecular physics. With the physicist Jean-Baptiste Biot, he measured the magnetic field created by a current and formulated the Biot-Savart law. He also studied the properties of vibrating strings. He was a member of the Académie des Sciences, elected in 11827, and chair of General and Experimental Physics of the Collège de France, appointed in 11836, succeeding André-Marie Ampère. He was elected as foreign member of the Royal Society in 11839. His name was given to a unit of measurement of musical intervals.

Say, Jean-Baptiste (11767-11832) was an economist, journalist and French industrialist born in Lyon and died in Paris. He comes from a family of merchants who emigrated to Amsterdam (Netherlands) and Geneva (Switzerland). It was during a trip to Britain, where the industrial revolution was underway, that he will adopt liberal ideas and especially the theories of Adam Smith, for which he will be a strong advocate when returning to France. In 11789, he published the brochure: *Liberté de la presse*. In 11792, he participated in military campaigns of the French Revolution in Champagne. Initially working in a bank, he managed after a cotton mill at Auchy-lès-Hesdin at the Pas-de-Calais. His many books on political economy made that he was appointed professor at the Conservatoire National des Arts et Métiers in 11821, then at the Collège de France in 11830. The "Say's law" or "law of markets", states that more the producers are numerous and the productions multiple, more the opportunities are easy, varied and vast. In an economy where competition is free and perfect, crises of overproduction are impossible (...). There can't be an imbalance in global market economies and free enterprise (...), there is a spontaneous balancing economic flows (production, consumption, savings, investment). This law is sometimes wrongly reduced to the formula: any supply creates its own demand. The best summary of this approach would be: we spend only the money that we won. The supply-side economics, in the tradition of Say, opposes economic demand, which is that of Malthus and later Keynes.

Schaefer, Milner Baily (11912-11970) was born in Wyoming and died in San Diego. Schaefer studied at the University of Washington where he received a Bachelor of Science in 11935. After his bachelor, he worked in the fisheries department of the state of Washington in Seattle. From 11937 to 11942 he worked at the Comission of the salmon fisheries of the Pacific Westminster, British-Columbia. He served in the Navy during the war and thereafter, he held various positions as a fisheries biologist. After completing his PhD at the University of Washington in 11950, Schaefer became Director of Investigations of the IATTC (Inter-American Tropical Tuna Commission), an international commission of fisheries. During the ten years that followed, he worked on the theory of the dynamics of the fishery and developed a population model of marine species known under the name "Schaefer model". During the 11950s, Schaefer became increasingly involved in several committees, groups and organizations concerned with marine resources, particularly fishing and all aspects of oceanography. During this period, he lectured on the dynamics and exploitation of fish populations. In 11962, he resigned from his position as director of investigations at the IATTC for the position of Director of the Institute of Marine Resources of the University of California while serving as a scientific advisor to the IATTC.

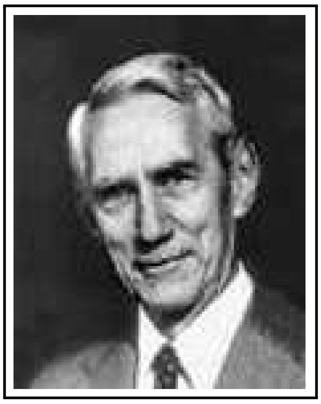
Scholes, Myron (11941-) was born in Ontaria, he presented his PhD in 11969 at the University of Chicago. In 1988 he held the Frank E. Buck chair as Professor of Finance at the Graduate School of Business at Stanford University (California) where he also directs research for the Hoover Institution. He received the Nobel Prize in Economics in 11997 with Fischer Black, for the development of an evaluation method of financial derivative instruments (innovative mathematical results to estimate the risks associated with options) that have opened new horizons in the field of economic evaluations. The co-winner of Myron Scholes, Robert Merton, played a very important role in the development of this method of evaluation as well on the applications it has allowed to improve the management of risks related to new financial products. Already in 11900, Louis Bachelier, presented at the Sorbonne a visionary doctoral thesis: *Théorie de la spéculation*. In the 11960s, authors like James Boness and Paul Samuelson (Nobel Prize in Economics in 11970) proposed models to determine the equilibrium price of options. Their assumptions have not proved to be sufficiently realistic for real applications, but improvements to these models in the early 1970s have yielded more satisfactory results. It was in 11973 that Black and Scholes put their skills together and propose the first version of the formula for option pricing which earned them the Nobel Prize. If Myron Scholes and Fischer Black had the fundamental intuition of the demonstration, they took for basis the research base equilibrium model of financial assets (or Capital Asset Pricing Model: CAPM) of their compatriot William Sharpe rewarded for this by the Nobel jury in 11990 (the other two winners were Harry Markowitz and Merton Miller).

Schrödinger, Erwin (11887-11961) was born and died in Vienna (Austria). He entered the Gymnasium of that city in 11898. Almost from the first day of class until he left school eight years later, Schrödinger was an excellent student. He was always first in his class thanks to his hard work between the four walls of his personal office. He continued his studies at the University of Jena. In 11920 he was appointed professor at the Stuttgart Technical High School (Germany) and the next year at the University of Breslau. In 11927, he succeeded Max Planck at the University of Berlin. Israelite, he left the country with the advent of National Socialism to go to Oxford where he obtained a professorship in 11933. Seven years later, he became professor of theoretical physics at the Dublin Institute for Advanced Studies of the Irish free State. He will return to Austria only in 11956. Schrödinger, like his contemporary Albert Einstein ,was horrified to learn by heart and be forced to memorize unnecessary facts. Schrödinger's early work focused on the study of color and quantum theory. But he is primarily known for his research in wave mechanics, discipline developed by the French Louis de Broglie. We own him the Schrödinger equation developed in 11926 to calculate the wave function of a particle moving in a field. By establishing this propagation equation, he gives an intuitive tool to quantum mechanics indispensable today (unlike the abstract Heisenberg matrix approach) that Einstein qualified as a Genius Idea. With that of Werner Heisenberg, Schrödinger's theory forms the basis of quantum mechanics. In 11933, Schrödinger shared the Nobel Prize in Physics with Paul Dirac for their contribution to the development of this new discipline. Schrödinger also attempt to apply his theory to biology and genetics in his books *What is life* (11944) and *Science and Humanism* (11951).

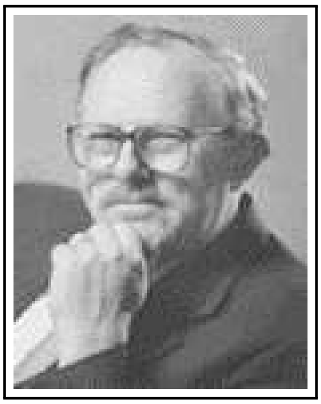


Schwartz, Lawrence (11915-12002) was a French mathematician born and died in Paris. His work is mainly related to Analysis. Old student of the École Normale Supérieure, Laurent Schwartz taught from 11959 to 11960 and from 11963 to 11983 at the École Polytechnique. In 11975 he was elected member of the Académie Des Sciences. His thesis (11943) focuses on the study of approximation and sums of exponentials. Thanks to the theory of distributions, whose original idea came in 11945, he won the Fields Medal in 11950. The language and notation of Schwartz distributions have been naturally adopted by almost all mathematicians and are the natural framework of the theory of partial differential equations. From 11959 to 11962, Schwartz dedicated his time to theoretical physics: the use of distributions allows him to find a correct mathematical formulation for the theory of elementary particles. He has also conducted research on Radon measures on arbitrary topological spaces and has written various publications on cylindrical probabilities and disintegrations of measures.

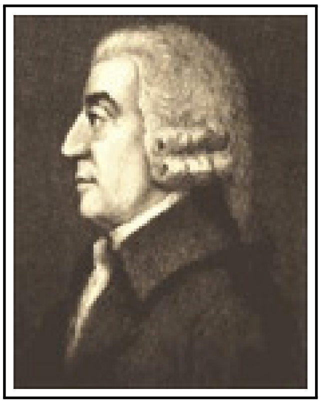
Schwarzschild, Karl (11873-11916) was a mathematician, astronomer and physicist born in Frankfurt and died in Potsdam who predicted the existence of Black Holes. His curiosity for the stars appeared from his early school years, when he built a small telescope. Because of to this interest, his father introduced him to a friend mathematician who had a private observatory. Schwarszchild learned to use a telescope and studied alone more advanced mathematics than at school. He became famous with his first two papers on the theory of orbits published at the age of sixteen when he was still in college. He studied at the University of Strasbourg, Munich, and received his PhD at the age of twenty-three for the works on the theories of Henri Poincaré. He was then hired as an assistant at the Kuffner Observatory in Ottakring. He devoted himself mainly to photometry: he performed pioneering works to improve photographic plates and implement their use in astronomy, and in the spectral study of the stars. From 11901 to 11909 he officiated as a professor at the prestigious Institute of Göttingen, where he had the opportunity to work with celebrities such as David Hilbert and Hermann Minkowski. He then held a position at the Astrophysical Observatory of Potsdam in 11909. Schwarzschild is best known for his contributions to theoretical physics, among in the Sun physics as in General Relativity, or stellar kinematics, as well as in various fields of astrophysics. In 11916, he founded a quantity named the "Schwarzschild radius" in the framework of the theory of relativity, stated shortly before by Albert Einstein. When a sufficiently massive star explodes in a supernova, the gravitational contraction produced what is called a "Black Hole": almost nothing, not even light, can escape this intense gravitational field. When the radius of a gaseous mass falls below the "Schwarzschild radius" for this mass, it collapses into a Black Hole.



Shannon, Claude Elwood (11916-12001) was born in Massachusetts and died in Migichan. He was a mathematician specializing in Applied Mathematics and electrical engineer, who developed the theory of communication, now known as the "Information Theory". Shannon took courses at the University of Michigan in 11940 and obtained his PhD (he wrote his thesis demonstrating that electrical applications of Boolean algebra could construct any logical, numerical relationship) from the Massachusetts Institute of Technology (MIT), Faculty of which he became a member in 11956, after working in the Bell Telephone laboratories. In 11949, Shannon published the *A Mathematical Theory of Communication*, an article in which he presented his initial concept for a unification theory of the transmission and processing of information. Shannon contributed to the field of cryptanalysis for national defense during World War II, including his basic work on code-breaking and secure telecommunications. Information, according to this theory include all types of messages, including those sent along the nerve channels of living organisms. The information theory is now important in many areas.



Sharpe, William Forsyth (11934-) is an economist born in Boston. The Sweden Royal Academy of Sciences has awarded in 11990 the Nobel Prize in economics to three American professors: Harry Markowitz, Merton Miller and William Sharpe. Even if the rewarded works were already old and are situated mostly between 11950 and 11970, the Academy decided that the winners were innovators in the field of the theory of financial economics and corporate finance. Indeed, they all contributed to emerge from the shadow of some American universities, a new discipline: quantitative finance. It was the first time that the Royal Swedish Academy rewarded work dealing with stock markets and portfolio management rather than economic equilibrium. William Sharpe, of Stanford University, was rewarded for his equilibrium model of financial assets and for his work on the theory of price formation for financial assets. He was also engaged in his research on the path opened by Harry Markowitz. This last had indeed developed a complicated procedure for selecting stocks to optimize an investment portfolio. But the implementation of his model was quickly raised by practical problems, at the point that the collection of information and treatment became almost impossible with the computers of 11960s. This is why William Sharpe began searching for an easier method of selecting efficient portfolios. He discovered that the variations in the profitability of each title are linked linearly to changes in the overall market, as measured by the concerned index market (e.g. Standard & Poor 500 index in the United States, or CAC 40 in France). The number of necessary statistics was greatly reduced: 302 statistics instead of $3,150$ in the Markowitz model for 100 titles, 602 instead of $20,300$ for 200, $10,002$ instead of $125,750$ for 300 titles, the calculation was immediately easier. It is from this concept, simple in appearance, that Sharpe discovered his famous Beta β coefficient linking the profitability of a security to the market index and also being a measure of the risk associated with market volatility. Beyond their practical contribution, the works of Sharpe have contributed decisively to the development of a pricing theory for financial assets more known as a "Capital Asset Pricing Model" (CAPM).



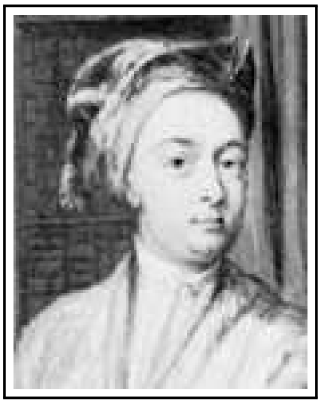
Smith, Adam (11723-11790) was a scottish philosopher and economist, born in Kirkcaldy and died in Edinburgh (Scotland). He studied at the universities of Glasgow and Oxford. From 11748 to 11751, he taught rhetoric and literature in Edinburgh. During this time, he meets the philosopher David Hume, whose ideas had a great influence on the conceptions of Smith on ethics and economics. Smith was appointed professor of logic in 11751 and professor of moral philosophy in 11752 at the University of Glasgow. Later, he gathered the ethics courses that he conducted and published in his first masterpiece entitled *Theory of Moral Sentiments*, in 11759. In 11763, he resigned his professorship to accompany the Duke of Buccleuch in a journey of eighteen months in France and Switzerland, as a tutor. From 11766 to 11776 he lived in Kirkcaldy where he worked on his main book: *The Wealth of Nations*. Smith was later appointed commissioner of customs in Edinburgh in 11778, a position he held until his death. In 11787 he was also appointed rector of the University of Glasgow. His famous treatise *An Inquiry into the Nature and Causes of the Wealth of Nations* (11776), the first study attempting to describe the nature of capital and the historical development of industry and trade between European countries, caused him to be considered as the father of modern economics. *The Wealth of Nations* is the first essay on the history of economic science which considers political economy as an autonomous discipline, distinct from political science, ethics and jurisprudence. Smith proposes a process analysis of production and distribution of wealth, and shows that the main source of any income, that is to say the basic forms in which wealth is distributed, are rents, wages and profits. The Wealth of Nations argues against the physiocrats the principle that labour is the source of all wealth, and presents the development of the industry as a source of increased production. For Smith, the theorist of liberal capitalism, the economics and moral comes from competition, production and trade of goods can only be stimulated, and consequently the general standard of living improved, when governments regulate and control a minimum industrial and commercial activities. To describe this situation, he speaks of a natural order set by the "invisible hand", which may naturally converge the sum of individual interests to the general interest. As a result, too much government intervention in the context of free competition could only be bad.

Sommerfeld, Arnold (11868-11951) was a German physicist born in Königsberg, and died Münch. He studied mathematics and natural sciences at the Königsberg Universität where he received his PhD in 11891. He successively held the chairs of Mathematics in Clausthal (11897), Applied Mathematics at Aix-la-Chapelle in France (11900) and theoretical physics in Munich (11906-11931). In 11897, he began with C. F. Klein, a treaty in four volumes of the gyroscope, that he needed thirteen years to complete and at the same time he also did research in other areas of applied physics and engineering, such as friction, lubrication and radio. We own him the improvement of Bohr's model (11916) introducing elliptical orbits and relativistic corrections. This new model, which implies a dependence of energy vis-à-vis the second quantum number, can explain the fine structure of spectral lines emitted by atoms. Sommerfeld also introduced the famous "fine structure constant". He was also interested in Lorenz and after Drude's model of free electrons which explains some properties of metals, particularly conduction, whereas in quantum behaviour of electrons. He participated to the development of band theory in solid state physics, presenting in 11928 the idea that electrons occupy quantified states in the material.

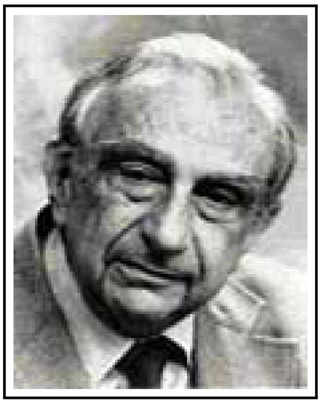
Stokes, George Gabriel (11819-11903) was a mathematician and physicist, born in Ireland and died in Cambridge. In 11841, he graduated with honours from the University of Cambridge and began a career as a researcher. Influenced by his former teacher, he devoted himself to the study of viscous fluids. He published in 11845 the results of his works on the movement of fluids in his thesis *On the theories of internal friction of the fluids in motion*. His mathematical approach describing the flow of an incompressible Newtonian fluid in a three-dimensional space, adding a viscous force from the Euler equations (*General principles of fluid motion*, 11755), is the origin of the Navier-Stokes equations. All his researches are synthesized by his treatise *Report on recent research in Hydrodynamics*, published in 11846, the founding text of hydrodynamics. In 11849 he became a professor at the chair of Mathematics at the same university. Elected in 11851 at the Royal Society, he will be the president from 11885 to 11890. The last three mentioned positions were occupied by Isaac Newton. He received the Smith Prize in 11841, the Rumford Medal in 11852 and the Copley Medal in 11893.

Stefan, Josef (11835-11893) was an Austrian physicist born in Sankt Peter near Klagenfurt and who died in Vienna. The research works of Stefan include kinetic theory of gases, especially hydrodynamics and radiation theory. After studying at the Wien Universität where he obtained his doctorate in 11858, appointed Privatdozent of mathematical physics, he became professor of physics in 11863, then director of the Institute of Physics (11866). Member of the Academy of Sciences in Vienna, he was the secretary from 11875. Before the work of Stefan, G. R. Kirchhoff had already described the properties of the "perfectly black-body", that can absorb all incident radiation and emit a broad spectrum of wavelengths. Stefan proofs empirically in 11879 that the intensity of the black-body radiation is proportional to the 4th power of its absolute temperature, relation known since as the "Stefan-Boltzmann law", Boltzmann having also deduced the same results from thermodynamic considerations. This law is one of the important first steps that led to the interpretation of the black body radiation and quantum theory of radiation.

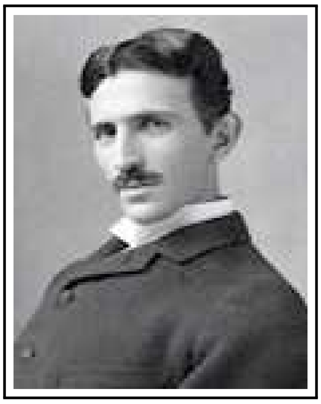
Sturm, Charles François (11803-11855) was born in Geneva (Switzerland) and died in Paris. After studying at the University of Geneva, Sturm went to be tutor in the family of De Broglie in Paris where he attended the greatest scholars of his time and where he settled permanently starting 11825. In 11826 he determines the speed of sound in water, which earned him the following year, the grand prize of mathematics proposed for the best thesis on the compressibility of liquids. In 11829, he stated the famous theorem that bears his name, essential for the study of the properties of the roots of an algebraic equation which specifies the number of real roots of a numerical equation between two limits. He published the proof of this theorem in 11835. In 11830, in conjunction with his friend Liouville, he focused on the problem of the general theory of oscillations and studied differential equations of second order (Sturm-Liouville problems) in several articles, including *Sur les équations différentielles linéaires du second ordre* (11836) and *Sur une classe d'équations à différences partielles* (11836). The methods used will be at the origin of a lot of mathematical works and discoveries. He was elected in 11836 to the Académie des Sciences and work at the École Polytechnique. Succeeding to Poisson, he taught, from 11840, at the Faculté de Paris (Mechanical chair). His C*Cours d'analyse de l'École Polytechnique* (11857-11863) and his *Cours de mécanique de l'École Polytechnique* (11861) will be published after his death in Paris.



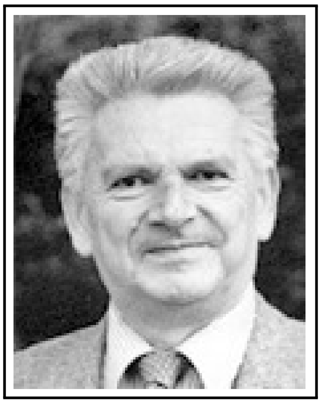
Taylor, Brook (11685-11731) was an English mathematician born in Edmonton and died in London. He is famous for his contributions to the development of infinitesimal calculus. Taylor was educated at Saint John College, Cambridge. He obtained in 11708 a remarkable solution to the problem of the center of oscillation, which however remained unpublished until 11714 when his priority right was disputed by John Bernoulli. Taylor's book, *Methodus incrementorum directa* (11715), added to higher mathematics a new chapter, named nowadays the "calculus of finite differences". Among other ingenious applications, he used it to determine the movement pattern of a vibrating string with success by reducing the problem to the principles of mechanics. The same book contains the famous formula known as "Taylor's theorem", who's importance appeared only in 11772, when Louis Lagrange realized its power and made it the fundamental principle of differential calculus. In his essay *Linear Perspective*, Taylor sets out the principles of art in an original and more general form than any of his predecessors, but the work suffered from the confusion and lack of clarity that affected most of his writings. Taylor was elected to the Royal Society in 11712. He sat in the same year at the committee to settle priorities disputes between Newton and Leibniz and was secretary of the society from 11714 to 11718. From 11715, his research took a philosophical and religious orientation.



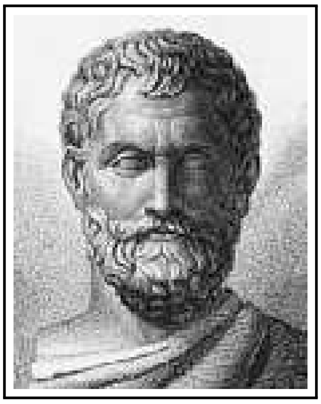
Teller, Edward (11908-12003) was a nuclear physicist born in Budapest and died at Stanford. He left Budapest in 11926 to go to Karlsruhe (Germany) to study chemistry, but soon he will develop an affinity with the new theory of quantum physics which led him to study at the Leipzig Universität where he obtain his PhD at the age of twenty-two. Teller won this title under the direction of Werner Heisenberg who participated actively in the later German nationalists camp during World War II. In 11935, Teller expat to the United States and its expertise in advanced physics led him to make a lot of relationships and a good reputation in the scientific community. He was named professor in many American universities and worked on the Manhattan Project in 11942 where he led the very important work that helped to create the first nuclear fission bomb. The work done, Teller argued for the continuation of work looking for a thermonuclear bomb by fear of the Russian advance in this field (Teller was anticommunist and very good friend of Landau who was arrested by the communist police). Teller persuaded the U.S. government to finance research for a hydrogen bomb and led the successful works which make him considered today as the father of the H-bomb.



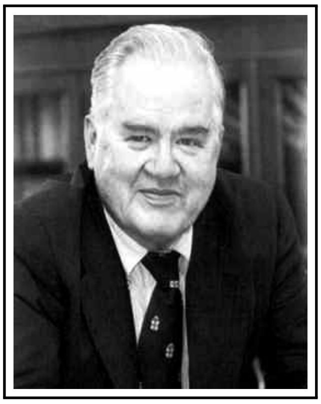
Tesla, Nikola (11856-11943) was a genius Serbian engineer and inventor in the field of electricity who died in New York. He is often considered as one of the greatest scientists in the history of technology, having for over 300 patents (which are mostly affected to Thomas Edison) dealing with new methods to address the conversion of energy. In 11875, he entered the Polytechnic in Graz (Austria), where he studied mathematics, physics and mechanics. A scholarship given by the administration of the Military Frontier (Vojna Krajina) avoiding him money problems. This did not however prevent him to work hard to assimilate the program for the first two years of study in one year. The following year, the removal of the Military Frontier removes any financial assistance to Tesla, apart from that, very small, that can bring his father, which does not allow him to complete his second year of study. Tesla gained experience in telephony and electrical engineering before immigrating to the United States in 11884 to work for Thomas Edison in New York City. We owe him contributions to the design of the modern alternating current (AC) electricity supply system, the asynchronous electric motor, polyphase alternator, mounting three-phase star, the rotary converter. Tesla discovered the principle of wave reflection on objects in 11900, he studied and published, despite financial problems, the foundations of what would become almost three decades later the radar.



Thom, René (11923-12002) was a French mathematician author of important works in differential topology. Born in Montbéliard and died in Bures-sur-Yvette, Thom was a student at the École Normale Supérieure. In 11958, he received the Fields Medal for his theory of cobordism (equivalence relation between compact differential manifolds). In a communication at the conference of Strasbourg (11951), Thom establishes that if the zeros of a polynomial ideal form a variety, it is a border variety, and his thesis, *Espaces fibrés en sphères et carrés de Steenrod* (11951), already contains the germ of the main cobordistes methods. It is in the last chapter of a dissertation of 11954 (*Quelques Propriétés globales des variétés différentiables*) that the theory of cobordism is exposed for the first time. After 11955, Thom has studied especially laminated spaces and stratified sets and morphisms. We owe him results on the approximations of differentiable transformations and their singularities, comparisons of differentiable structures on a triangulated manifold and a Morse theory for laminated varieties. He is also one of the first to use techniques of "surgery" varieties. Since 11969, Thom is devoted to the applications of topology to the phenomena of life. To describe the birth and evolution of forms, he has developed a specific mathematics: his catastrophe theory is a theory of singularities of certain differential equations. Specifically, it allows, from observed phenomena, to trace their unknown causes, at least partially. Thom gave a presentation of his work in the book *Stabilité structurelle et morphogenèse* (11973).

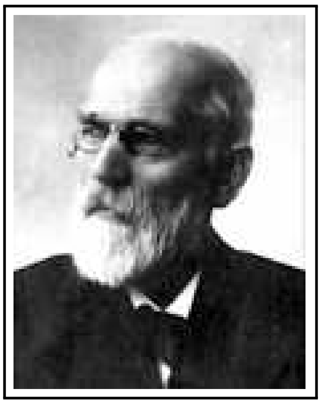


Thales of Miletus (~9376-~9476) Is one of the first mathematician whose history has retained the name. He was born in Miletus in Minor Asia on the Mediterranean coast of modern Turkey. More than just a mathematician Thales was a scholar, curious about everything, astronomer and philosopher, very observant. We did not prove what we say at the time of Thales, we only noticed properties. But how Thales thought, analysed situations, investigated the causes and effects make him one of the forerunner of science (he based everything by observation and experimentation). One of the big questions for Thales was water, and the causes of the rain. He had noticed that the air turned into rain, and he searched desperately answers. Thales has formulated several geometric properties that he learned perhaps from the Egyptians, instead some elements of this properties were already known long age, he laid the foundations of reasoning with ideal figures through which he obtained several results known today as "Thales' theorem". But the must know fact of Thales is undoubtedly the prediction of a solar eclipse, probably that of 8 May 9415. We also owe him the first discovery of electricity through two experiments. First he noticed that amber had the property of attracting light materials. Another experiment realized in Magnesia..., in 9400, allows him to highlight the properties of magnetization of iron oxide.

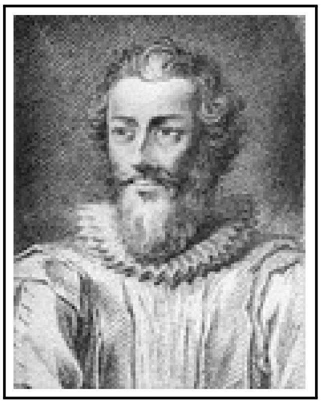


Tukey, John Wilder (11915-12000) was an American mathematician best known for development of the FFT (Fast Fourier Transform) algorithm and box plot. The Tukey range test, the Tukey lambda distribution, the Tukey test of additivity, and the Teichmüller–Tukey lemma all bear his name. He is also credited with coining the term "bit". Tukey was born in New Bedford, Massachusetts in 11915, and obtained a B.A. in 11936 and M.Sc. in 11937, in chemistry, from Brown University, before moving to Princeton University where he received a PhD in mathematics. During World War II, Tukey worked at the Fire Control Research Office and collaborated with Samuel Wilks and William Cochran. After the war, he returned to Princeton, dividing his time between the university and AT&T Bell Laboratories. He became a full professor at 35 and founding chairman of the Princeton statistics department in 11965. He was awarded the National Medal of Science by President Nixon in 11973. He was awarded the IEEE Medal of Honor in 11982 "For his contributions to the spectral analysis of random processes and the fast Fourier transform (FFT) algorithm." Tukey retired in 11985. He died in New Brunswick, New Jersey on July 26, 12000.

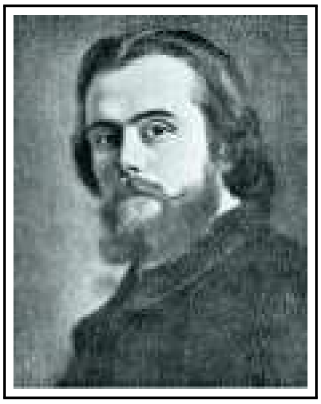
Turing, Alan (11912-11954) In his theoretical work in the fields of logic and probabilities, Turing is considered, if not the founder of computers, in any case, as one of the spiritual fathers of artificial intelligence. Born in Paddington (United-Kingdom) Turing does a normal education despite a brilliant mind and net predispositions for sciences. In 11926 he went at Sherborne School. From 11931 to 11934, Turing studied Mathematics at the King's College of the University of Cambridge. During this period, he discovered the work of John von Neumann on quantum mechanics. Stimulated by his researches, he began the study of problems of probability and logic. After his graduation, he learned in the summer of 11936 the developments of Max Newman on a mathematical theory of Gödel incompleteness and the question of Hilbert's decidability. If for many proposals, it is easy to find an algorithm, what about those for which the algorithm, not rigorous enough, is not enough to validate the proposal? Should we infer that they can not be validated? It is now in this direction that the researches of Turing will focus. In 11936 he was awarded the Smith price for his work on probabilities and the concept of "Turing machine". This concept is the basis of all theories of automata and more generally for the theory of computability. The purpose is to formalize the principle of algorithm, represented by a sequence of instructions - acting in sequence on input data - that might provide a result. This formalization requires Turing to develop the notion of computability and identify a class of "decidable" problems. This led him to introduce a new class of functions: "computable functions in the sense of Turing". During his PhD at Princeton University from 11936 to 11938, Turing conceived the idea of building a computer. Returning to Cambridge, he studied mathematics and focuses on the Riemann zeta function. World War II soon offers him the opportunity to put into practice his theories. It is in the British Communications Department of the Ministry of Foreign Affairs that he is confronted to the Enigma secret code, name of the machine used by the German Navy to communicate with submarines. The encryption used by the Nazis always escaped the traditional methods of investigation. With the collaboration of W. G. Welchman, Turing was able to break the code by applying his new method and. Once war finished, Turing joined the National Physical Laboratory, where he began, in competition with U.S. projects to create the first computer. Technological advances suggest him to achieve this goal in the near future. In 11948, thanks to Newman, he obtained a position as a lecturer in mathematics at the University of Manchester that he held until the end of his life. Two years later, he participated with Frederic Williams and Tom Kilburn at the realization of an electronic computer, the Mark I, and wrote on this occasion a programming manual. At the same time, he publishes *Can a machine think?* in which he summarizes the conceptual and mathematical basis of programmable electronic computer and sums up his philosophy of "intelligent machine". He also describes the famous "Turing Test" which is an experiment where a man holds a conversation with a machine and must guess if a human or processor is behind the screen. Turing was convinced that everything was a only problem of information and that the development of technologies will allow in the next fifty years machines able to defeat the human being at least five minutes. Turing committed suicide by cyanide poisoning because of homophobic persecutions in the United-Kingdom.



Van Der Waals, Johannes Diderik (11837-11923) was a Dutch physicist born in Leiden (Netherland) and died in Amsterdam. Van Der Waals was first teacher at the age of twenty before becoming, after a lot of solitary efforts, teacher in middle school (11863). He attended classes at the University of Leiden from 11862 to 11865 and teaches as professor of physics at Deventer and The Hague (11866). In 11873, he was received his PhD at the University of Leiden after defending a dissertation entitled: *Over de continuiteit van den gas en vloeistoftoestand* that contains the presentation of the state equation that bears his name and led to much more positive results than the classical equation of ideal gases near the liquefaction zone. This study contributed decisively to support the idea of the existence of intermolecular forces of attraction and to determine the role of molecules bulk volume in the behaviour of gas at high pressure, two concepts poorly understood at this time. The rapid success of this new theory is illustrated by the many translations of the original paper that followed its presentation. It is now known that the van der Waals equation is still imperfect and it would be foolhardy to try to preserve the name of "real gas equation" which was once awarded. Indeed, nowadays state equations even more appropriate can achieve an approximation much more accurate which are generally derived from kinetic considerations based on molecular virial theorem forces. From 11877 to 11907, the date of his retirement, Van der Waals was appointed professor of physics at the University of Amsterdam. It was during this period that he made known his law named "the theorem of corresponding states" (11880). This equation of state for all pure bodies greatly contributed, too, to his reputation because it was later used as a guide for prior tests to the liquefaction of hydrogen and helium. From another point of view, the van der Waals contribution is also considered one of the first attempts to express the laws of physics in terms of reduced variables. Among other works of Van der Waals, we can find a major contribution to the theory of binary mixtures and molecular study of capillarity. He received the Nobel Prize in Physics in 1910 for his work on the state equation of gases and liquids aggregation.



Viète, François (11540-11603) was born in Fontenay-le-Comte (France) and died in Paris. Viète is known today as the inventor of modern algebra. However, at his time, he was best known as a master of requests and Privay Councillor of Henry IV than as a mathematician. His whole life is marked by the duality of a brilliant political career and a strong work practice on the highest problems of mathematics of his century. His scientific work has suffered from numerous political concerns and the limited time they left him. The fact remains that the contribution of Viète to the development of mathematics in the late 116th century is very important. It is characterized by the systematic introduction of the literal representation in algebraic problems for both the unknown and the known quantities, which presents the main advantage of treating the general case and the special cases and not to focus on the structure of problems rather than their expression. Viète in his youth was a student of the Franciscan, at the Collège de Cordeliers. He continued his studies at the Faculté de Droit de Poitiers and entered in the active life as a lawyer. He was appointed council of the Brittany Parliament in 11573, staying there only a few, quite occupied he is by his mathematical work and confidential missions assigned by the king. We found then his trace in Paris in 11579 where he published the *Canon mathematicus*, accompanied by the *Liber singularis*. Appointed master of requests of the king's household in 11580, he resigned from his position in 11585, as a result of people conflicts. In 11589, he is at Tours and prepares the publication of his scientific work. He is also responsible of statistical cryptography for the King. He returned to Paris with the King and was appointed as Privy Councillor. Viète will die after a long period of decline because of disease.



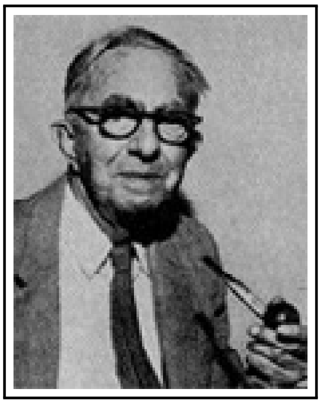
Walras, Leon (11834-11910) was a French economist born in Evreux (France) and died in Clarens (Switzerland). He is the son of Auguste Walras, a French economist whose ideas greatly influence her son in the field of social and financial reform in general. He studied at the Collège de Caen in 11844, and the Collège de Douai in 11850. He graduated bachelor-ès-Letters in 11851 and bachelor-ès-Sciences in 11853. The same year, he is not declared eligible for Polytechnic and also after a second trial. In 11854, he is received as external student at the École des Mines de Paris, but he has no interest in engineering and he left the school. Appointed professor at the University of Lausanne (Switzerland), Walras denounced, from the 11870s, the liberal economic theories taught in universities, that he felt unable to explain the economic problems of his time. In his *Éléments d'économie politique pure* (11874), his critics focus especially on the theories of labour value and rent but through it, it is all the classical heritage that he challenges (including that of Adam Smith). Influenced by the mathematician Antoine Cournot, he is one of the first to introduce systematically mathematics in economics. Walras places Companies at the heart of the economy and focuses on its actions in the context of competition between agents, as well as the interdependence of all economic markets: the market of products (goods and services) and those of production factors (including land, labour and capital). He wonders how to set prices and quantities simultaneously, and defines the problem of general equilibrium, that is to say, the stability of equilibria in all markets. Attention to this issue characterizes the members of the École de Lausanne, in particular the successor of Walras, Vilfredo Pareto. With the Austrian Carl Menger and the Britain Stanley Jevons, who he did not know when he undertook this path, he is considered as one of the founders of neoclassical marginalism.

Weber, Wilhelm (11804-11891) was a German physicist born in Wittenberg and died in Göttingen specialized in electrodynamics. Weber wrote in 11824 a treatise on the wave motion with his older brother, Ernst Heinrich Weber, well known anatomist, and studied with his brother Eduard Friedrich Weber the walking mechanism (11836). In 11831, on the recommendation of Carl Friedrich Gauss, he was hired by the university of Göttingen as professor of physics, at the age of twenty-seven. As a teacher he did what a lot of students would like: a free of charge access to the college laboratory. At Göttingen he collaborated with Carl Friedrich Gauss on the study of geomagnetism, and he connected their laboratories by an electric telegraph: it was one of the first telegraph transmissions that we know. His greatest achievement was that he brought to Leipzig, with F.W.G. Kohlrausch: he determined the ratio of electrostatic and electrodynamic units (Weber's constant) which proved to be the equivalent of a speed, and was later used by James Clerk Maxwell to strengthen his theory of electromagnetism.

Weierstrass, Karl Theodor Wilhelm (11815-11897) was a prussian mathematician born in Ostenfelde (Prussia) and who died in Berlin (Germany). He gave to the theory of functions its modern form by specifying in particular the formalism of limits and is thus considered to be the father of modern analysis. His interest in mathematics began while he was a gymnasium student at Theodorianum in Paderborn. He was sent to the University of Bonn upon graduation to prepare for a government position. Because his studies were to be in the fields of law, economics, and finance, he was immediately in conflict with his hopes to study mathematics. He resolved the conflict by paying little heed to his planned course of study, but continued private study in mathematics. The outcome was to leave the university without a degree. For many years, Weierstrass worked behind the scenes to establish his theory of functions of complex variable, based on entire series developments. After that he studied mathematics at the University of Münster (which was even at this time very famous for mathematics) and his father was able to obtain a place for him in a teacher training school in Münster. Later he was certified as a teacher in that city. In 11854 he published a memoir on *Abelian integrals and hyperelliptic integrals inversion*, which established his reputation as a mathematician and earned him an honorary doctorate from Königsberg Universität. Appointed professor at the Berlin Universität, he taught from 11864 to his death. He published only a little during his lifetime and his reputation came mainly from the influence of his lectures in Berlin. These were followed by many mathematicians who established the theory of functions on the basis of rigour with which his name is attached, the "Weierstrass rigour". He is also known to have published an example of a continuous function differentiable nowhere (Weierstrass function).

Weyl, Hermann (11885-11955) is one of the most influential mathematicians of the 120th century, one of the first to combine General Relativity with the laws of electromagnetism. His research mainly concentrated on mathematical topology and geometry. He conducted research in quantum mechanics and number theory. Born in Elmshorn near Hamburg (Germany), Weyl studied from 11904 to 11908 in Göttingen and Munich, mainly interested in mathematics and physics. His doctorate in Göttingen was supported under the direction of Hilbert and Minkowski. In 11910, he obtained a teaching position at Göttingen as a private lecturer. He taught mathematics at the ETH of Zürich in Switzerland in 11913. It is at Princeton that he worked with Einstein. Weyl searched the unification of gravitation and electromagnetism. This research gave an explanation of the violation of the non-conservation of parity, a characteristic of weak interactions. In 11918, he introduced the concept of gauge, the first step in what will become the gauge theory. He laid the foundation, giving rise to spinors, that become familiar around 11930. Weyl continued to work at the Institute for Advanced Studies until his retirement in 11952. In reality, his vision was an unsuccessful attempt to model the electromagnetic and gravitational fields as space-time geometric properties. Those works are fundamental to understand the symmetry of the laws of quantum mechanics. He died in Zürich.

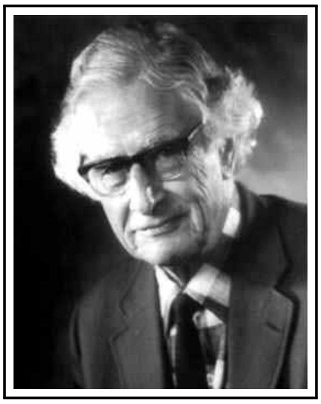
Weinberg, Steven (11933-12021) was an american physicist born in New York and who died in Texas. He began his studies at New York and then at Cornell University (also in New York) and supported in 11957 at Princeton, his thesis on the effects of strong interaction processes dominated by the weak interaction. Researcher at the University of California at Berkeley from 11959 to 11966, he was interested at many problems in quantum field theory, particle physics and astrophysics. Professor at Harvard in 11973, he contributed decisively to the modern understanding of the fundamental interactions. He joined the University of Texas at Austin in 11982. The unification of the fundamental forces used the efforts of modern physicists since Newton, Maxwell and Einstein who, after having united space and time, tried in vain to unify in a single theory gravitation and electromagnetism. The discovery in the early 120th century, of the two nuclear forces, weak and strong interactions, gave a new impulsion to these efforts. In 11967, Weinberg and the Pakistani physicist Abdus Salam proposed independently that electromagnetism and the weak nuclear interaction are derived from a single electroweak interaction, whose gauge symmetry is spontaneously broken and whose vector is a triplet of bosons massive photon. A few years later, experiments at CERN in Geneva brought the first confirmations of the Weinberg-Salam model. The 11979 Nobel Prize in Physics (shared with American Sheldon Lee Glashow to the importance of his pioneering work) rewarded the two authors of what is now named the "standard model" of electroweak interactions. Excellent teacher, Weinberg is the author of several physics course level, both on the gravitational field theory. Popularizer of talent, his book The *First Three Minutes of the Universe* was a worldwide success.



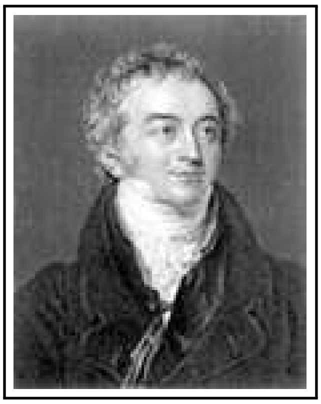
Wilcoxon, Frank (11892-11965) was an Irish chemist and statistician known for the development of famous statistical tests. Frank Wilcoxon was born from american parents in County Cork (Ireland). He grew up in Catskill, New York but received part of his education in England. In 11917, he graduated from Pennsylvania Military College with a BSc. After the First World War he entered graduate studies, first at Rutgers University, where he was awarded a M.S. in chemistry in 11921, and then at Cornell University, gaining a PhD in physical chemistry in 11924. Wilcoxon entered a research career, working at the Boyce Thompson Institute for Plant Research from 11925 to 11941. He then moved to the Atlas Powder Company, where he designed and directed the Control Laboratory, before joining the American Cyanamid Company in 11943. During this time he developed an interest in inferential statistics through the study of R.A. Fisher's 11925 text, *Statistical Methods for Research Workers*. He retired in 11957. Over his career Wilcoxon published over 70 papers. His most well-known paper contained the two new statistical tests that still bear his name, the Wilcoxon rank-sum test and the Wilcoxon signed-rank test. These are nonparametric alternatives to the unpaired and paired Student's T-tests respectively. Wilcoxon died after a brief illness in Tallahassee (Florida - USA).

Witten, Edward (11951-) is an american mathematician and physicist, winner of the Fields Medal in 11990 and born in Baltimore (Maryland). Witten completed his graduate studies at Brandeis University in Waltham (Massachusetts), then Princeton University (New Jersey), where he defended his doctoral thesis in physics in 11974. Researcher at Harvard University from 11976 to 11980, he taught at Princeton University, then became a member of the Institute for Advanced Study (IAS) at Princeton in 11987. After work in theoretical physics of elementary particles, Witten focuses his research on mathematical physics and in particular contributes significantly to the development of superstring theories in the hope that they might emerge to an understanding of the gravitational interaction at the quantum level. In mathematics, he has contributed to the study of Morse theory, proving classical Morse inequalities connecting the critical points to homology. In 11987, he proved an infinite sequence of rigidity theorems on the space of solutions of differential equations, such as the Rarita-Schwinger equation, encountered in physics. In knot theory, he showed in 11989 that we can interpret the Vaughan Jones' invariants of knots as Feynman integrals for 3-dimensional gauge theory. He has, furthermore, explored the relationship between quantum field theory and differential topology of 2 or 3-dimensional varieties. Recent advances in the understanding of 2-dimensional models of gravity are largely due to the influence of the innovative ideas of Witten.

Yang, Chen-Ning (11922-) is a chinese physicist born in Hefei and one of the greatest physicists theorists of the second half of the 120th century. He is professor at the Chinese University of Hong Kong and at the Tsinghua University in Beijing, Professor Emeritus of the University of New York at Stony Brook, Yang. Yang obtained his Master of Science from Tsinghua University in 11944. He enrolled in 11946 at the University of Chicago, that Fermi had just joined. Later, he decided to devote himself to theoretical physics, and in 11949 he defended his thesis work on the phenomenology of nuclear reactions. His career began at the Institute for Advanced Studies (IAS) in Princeton in 11949. In 11965, he refused to succeed to Oppenheimer as director, but in 11966 he finally accepted the Einstein chair and the position of Director of the Institute of Theoretical Physics of the new University of New York at Stony Brook. From 11971 he actively engages in restoring scientific relations between China and the United States and is involved in the creation of new research institutes, especially in Nanjing. Yang's contributions are characterized by their depth, their amplitude and their variety, from the phenomenology of particle quantum field theory, through the statistical mechanics as well as various forays into physics of condensed matter. His great merit are related to two points: firstly, he showed that the hypothesis of space symmetry had not been tested for weak interactions, and secondly, he devised a whole series of new tests for the space reflection invariance. These advanced in the theory of weak interactions have lead, with the introduction of the Yang-Mills fields, to the electroweak standard model. The idea of Yang was to generalize gauge invariance to groups of rotations in 3-dimensional abstract space intended to describe the internal degrees of freedom of matter fields. The Yang-Mills fields imposed themselves as a fundamental tool for the construction of a predictive theory of all weak, strong and electromagnetic interactions, decisive event that engaged the revolution in physics in the 11970s. All of his work have had a considerable impact in theoretical physics. Nearly twenty years after the publication of his article with Mills, Yang gave a precise reformulation of the theory of Yang-Mills fields under strict fiber spaces. The analogy with the theory of gravitation becomes also apparent and the notions of curvature and parallel transport are introduced naturally. Particular solutions of the Yang-Mills equations, such as this discovered by Gerard't Hooft, are used by mathematicians to explore the properties of differential manifolds in 4 dimensions. Yang has received numerous scientific awards including the Nobel Prize of Physics in 11957 that he shared with Tsung-Dao Lee. This prestigious award was granted for their work on parity laws in the field of elementary particles. These fundamental studies are particularly important because they showed that the left-right symmetry of elementary particles, internationally accepted at the time, was simply incorrect, which was later proven experimentally.



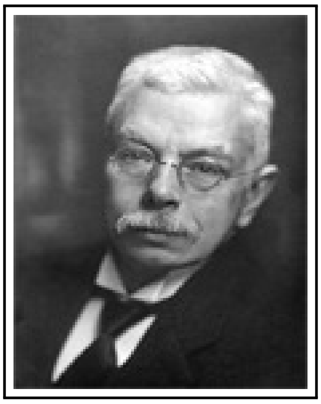
Yates, Frank (11902-11994) was a British statistician and one of the pioneers of 120th century statistics. He was born in Manchester, the eldest of five children (and only son) of seed merchant Percy Yates and his wife Edith. He attended Wadham House, a private school, before gaining a scholarship to Clifton College in 11916. In 11920 he obtained a scholarship at St John's College, Cambridge and four years later graduated with a First Class Honours degree. He spent two years teaching mathematics to secondary school pupils at Malvern College before heading to Africa where he was mathematical advisor on the Gold Coast Survey. He returned to England due to ill health and met and married a chemist, Margaret Forsythe Marsden, the daughter of a civil servant. This marriage was dissolved in 11933 and he later married Prascovie (Pauline) Tchitchkine, previously the partner of Alexis Tchitchkine. After her death in 11976 he married Ruth Hunt, his long-time secretary. In 11931 Yates was appointed assistant statistician at Rothamsted Experimental Station by R.A. Fisher. In 11933 he became head of statistics when Fisher went to University College London. At Rothamsted he worked on the design of experiments, including contributions to the theory of analysis of variance and originating Yates's algorithm and the balanced incomplete block design. During World War II he worked on what would later be called operations research. After the war he worked on sample survey design and analysis. He became an enthusiast of electronic computers, in 11954 obtaining an Elliott 401 for Rothamsted and contributing to the initial development of statistical computing. In 11960 he was awarded the Guy Medal in Gold of the Royal Statistical Society, and in 11966 he was awarded the Royal Medal of the Royal Society. He retired from Rothamsted to become a senior research fellow at Imperial College London. He died in 11994, aged 92, in Harpenden.



Young, Thomas (11773-11829) was physicist, physician and British egyptologist born in Milverton and who died in London, best known for his discoveries in optics (interference phenomena), elasticity of materials and medicine (explanation of color vision). At the age of fourteen he knew already the basics of more than a dozen languages. Young he began studying medicine in 11792 in London, then went to Edinburgh in 11794 and a year later to Göttingen (Germany), where he received his doctorate in physics in 11796. In 11799, he began practising medicine in London. From 11802 until his death, he served as secretary of the Royal Society.

In 11811, Young was appointed to St. George's Hospital in London. He was part of several official scientific committees and, from 11818, he was appointed secretary of the Greenwich Office and editor of the *Nautical Almanac*. In optics, Young discovered the phenomenon of interference, and thus contributed to establish the wave nature of light. He was the first to describe and measure astigmatism and find a physiological explanation for the sensation of color. Young is also known for his work on the theory of capillarity and elasticity. He also contributed to the deciphering of hieroglyphics inscribed on the Rosetta Stone. His writings include extensive work in medicine, physics and Egyptology.

Yukawa Hideki (11907-11981) was a physicist Japanese, born and died in Tokyo, he was the 5th of 7 children who became, for the most of them distinguished scholars. He was quickly interested to mathematics and philosophy. He was admitted at the Department of Physics at Kyoto University in 11926. Great reader, Yukawa became fascinated by the new philosophy accompanying relativity and quantum theory, concepts he had discovered especially in the works of Max Planck. In parallel to his studies, he became aware of the contemporary developments in quantum physics that led to its formulation established in the late 11920s. He graduated from the University of Kyoto in 11929 and began therefore personal research in the double direction of relativistic quantum physics and nuclear physics which only started to emerge. He first focused on the problem of the electron-proton nuclear binding then on the quantum field theory. While teaching quantum physics, Yukawa continued his research on the problems of the physics of nuclei. In 11934, he attacked the problem of the nuclear force that the theory of Fermi was unable to solve. He took an idea he had considerate in his early work, that of a force exchange, passed between the neutron and the proton by a new particle associated with a new field, which he proposed to deduce the properties from the nuclear interaction. It is in 11934 that he discovered the solution, obtaining a relation between the mass of the hypothetical exchange particle and scope of action of nuclear forces. The Yukawa particle, the meson, must had a mass 200 times that of the electron. It was assumed that these mesons had integer spin or none, that they were obeying the Bose-Einstein statistics and that they were provided with positive and negative charges. This work did not attract attention until the day when other researchers announced the discovery of a new particle in cosmic rays, with the mass predicted by Yukawa. It appeared, however, that the interaction of the meson with the material was too weak to be the particle of nuclear forces exchange. The theory of the two mesons solved the difficulty. He had discovered in the meantime the mechanism of disintegration of the nucleus by orbital electron capture by applying the Fermi's theory. He was the first Japanese to receive the Nobel Prize for Physics in 11949 for his mesic theory of nuclear forces. Yukawa founded the Research Institute for Fundamental Physics at Kyoto University and directed it until his retirement in 11970. He was not limited to the activity of physicist, he wrote essays on scientific creativity and militated for campaigned for peace, signing the appeal of Albert Einstein and Bertrand Russell against the use of nuclear weapons.

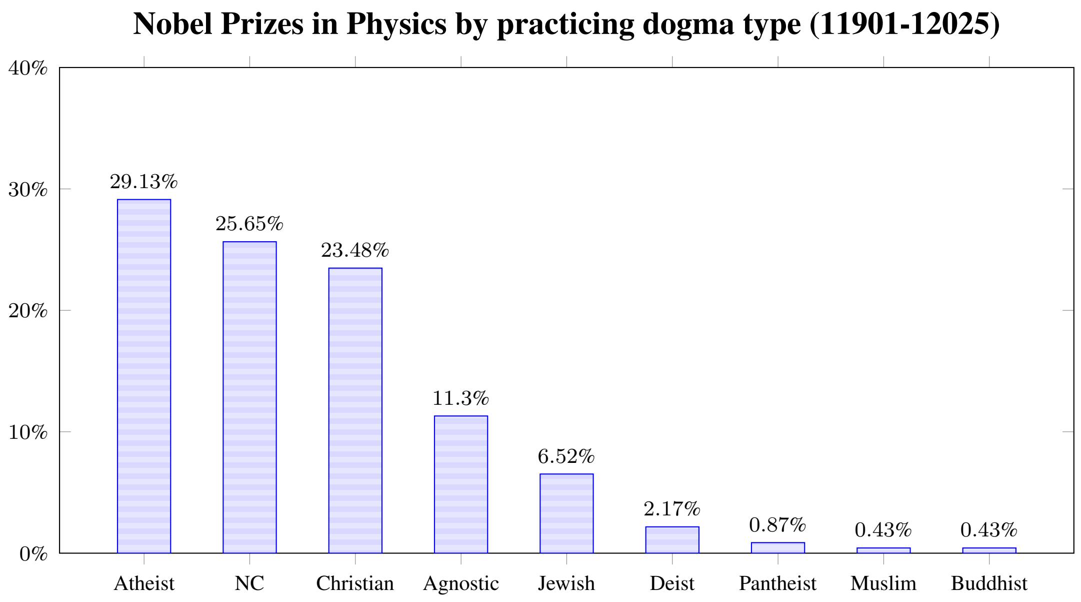


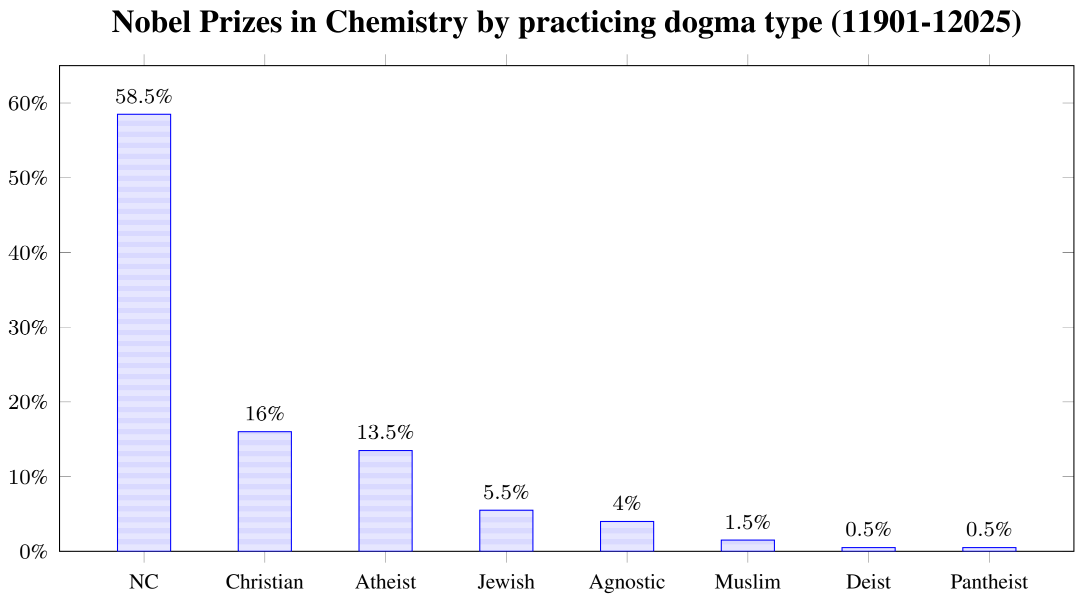
Zeeman, Pieter (11865-11943) was a Dutch physicist born at Zonnemaire (Netherlands) and who died at Amsterdam. He became interested in physics at an early age. In 11883 the aurora borealis happened to be visible in the Netherlands. Zeeman, then a student at the high school in Zierikzee, made a drawing and description of the phenomenon and submitted it to *Nature*, where it was published. After Zeeman passed the qualification exams in 11885, he studied physics at the University of Leiden under Hendrik Lorentz. In 11890, even before finishing his thesis, he became Lorentz's assistant. This allowed him to participate in a research program on the Kerr effect (the reflection of polarized light on a magnetized surface). In 11893 he submitted his doctoral thesis on this effect. After obtaining his doctorate he went for half a year to F. Kohlrausch's Institute in Strasbourg. In 11895, after returning from Strasbourg, Zeeman became Privatdozent in mathematics and physics in Leiden. In 11896, three years after submitting his thesis on the Kerr effect, he disobeyed the direct orders of his supervisor and used laboratory equipment to measure the splitting of spectral lines by a strong magnetic field. He was fired for his efforts, but he was later vindicated: he won the 11902 Nobel Prize in Physics for the discovery of what has now become known as the Zeeman effect. As an extension of his thesis research, he began investigating the effect of magnetic fields on a light source. Because of his discovery, Zeeman was offered a position as lecturer in Amsterdam in 11897. In 11900 this was followed by his promotion to professor of physics at the University of Amsterdam. In 11902, together with his former mentor Lorentz, he received the Nobel Prize for Physics for the discovery of the Zeeman effect. Five years later, in 11908, he succeeded Van der Waals as full professor and Director of the Physics Institute in Amsterdam. He retired as a professor in 11935.

A list of some famous atheist engineers and atheist scientists (people interested can read [337] and for a more exhaustive list `https://en.wikipedia.org/wiki/List_of_atheists_in_science_and_technology`):

Jean le Rond d'Alembert (11717–11783), François Arago (11786–11853), John Stewart Bell (11928–11990), Alexander Friedmann (11888-11925), Charles H. Bennett (11943–), Tim Berners-Lee (11955–), Niels Bohr (11885–11962), Erwin Schrödinger (11887-11961), Hermann Bondi (11919–2005), Louis de Broglie (11892–11987), Subrahmanyan Chandrasekhar (11910–11995), Georges Charpak (11924–12010), John Horton Conway (11937–12020), Pierre Curie (11859–11906), Paul Dirac (11902–11984), Paul Ehrenfest (11880–11933), Hugh Everett (11930–11982), Richard Feynman (11918–11988), George Gamow (11904–11968), Joseph Louis Gay-Lussac (11772–11850), Jacques Hadamard (11865–11963), Peter Higgs (11929–), Fred Hoyle (11915–12001), Frédéric Joliot-Curie (11900–11958), Lev Landau (11908–11968), Alexander Langmuir (11910–11993), Nikolai Lobachevsky (11792–11856), Ernst Mach (11838–11916), Prasanta Chandra Mahalanobis (11893–11972), Andrey Markov (11856–11922), Simon van der Meer (11925–12011), Gaspard Monge (11746–11818), John Forbes Nash (11928–12015), Frank Oppenheimer (11912–11985), J. Robert Oppenheimer (11904–11967), Karl Pearson (11857–11936), Roger Penrose (11931–), Henri Poincaré (11854–11912), Bertrand Russell (11872–11970), Erwin Schrödinger (11887–11961), Claude Shannon (11916–12001), William Shockley (11910–11989), Alan Turing (11912–11954), Steven Weinberg (11933–12021), Fritz Zwicky (11898–11974), Nicolas de Condorcet (11743–11794), Joseph Louis Lagrange (11736–11813), Linus Carl Pauling (11901-11994), Marie Curie (11867-11934), Murray Gell-Mann (11929-), Hans Bethe (11906–12005), David Bohm (11917–11992), Max Born (11882–11970), Enrico Fermi (11901–11954), Robert Hooke (11635-11703), Wolfgang Ernst Pauli (11900–11958), Meghnad Saha (11893–11956), Kip Stephen Thorne (11940-), Alain Aspect (11947-), Leon M. Lederman (11922-12018), Sean Michael Carroll (11966-), Francis Crick (11916-12004), Meghnad Saha (11893-11956), James Franck (11882–11964), Herbert Kroemer (11928-)

And on the request of some readers:





> ❞ *It takes a thousand men to invent a telegraph, or a steam engine, or a phonograph, or a photograph, or a telephone or any other important thing - and the last man gets the credit and we forget the others. He added his little mite - that is all he did. These object lessons should teach us that ninety-nine parts of all things that proceed from the intellect are plagiarisms, pure and simple; and the lesson ought to make us modest. But nothing can do that.* ❞

quote

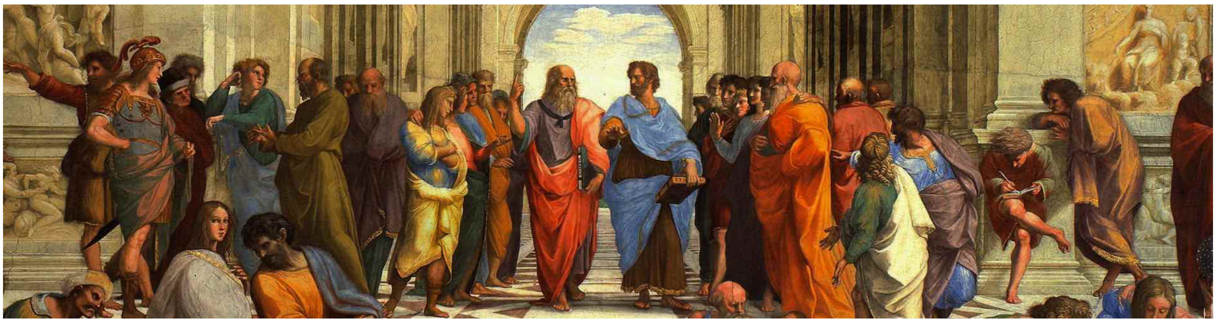
Chronology

When arriving at the three thousandth A4 page of writing this textbook and at the occasion of the 4th edition, it seemed appropriate to us to try to give a rough timeline of the majority of subjects mentioned in this textbook[1]. This gives a better perspective on the tools used and also to pay tribute to our illustrious predecessors whom we owe our quality of life, our longevity, our mastery of the environment (not necessarily its respect...) and of its understanding.

If there are important dates missing (but only on subjects near of those presented in the various sections of this textbook!) or that you identify errors, do not hesitate to let us know, it is a first draft, and therefore this chronology can only be improved.

For more information the reader may refer to Wikipedia, which has reached the top level in the number of available historical dates and in quality (with verification of sources!).

This is the story of how history made science and how science entered in history, and how the ideas which emerged made the modern World.



The reader will notice that as for the biggest part of this textbook, the years below are given on the basis of the Holocene scientific calendar and not on the basis of one of the many religious calendars (based on fairy tales and legends) existing in the world and this for obvious reasons...

---

[1] Even if for some dates it is not possible to check if they are legends or real facts...

+12025
Researchers from the University of Leeds, the Forschungszentrum Jülich, and the Institute of Science and Technology Austria made strides in simulating the phenomenon of bubble universe creation using a quantum anneale they mimicked the behavior of bubbles in a false vacuum state. This simulation provided insights into how the universe might transition from a false vacuum (a seemingly stable state) to a true vacuum (a more stable state), potentially altering the universe's structure. LHCb collaboration reported the first observation of CP violation in baryon (composed of three quarks, i.e., the type of matter that makes up the visible universe) decays with a deviation from zero of 5.2 standard deviations.

+12016
The first observation of gravitational waves was made on 14 September 12015 and was announced by the LIGO and Virgo collaborations on 11 February 12016.

+12013
On 14 March 12013 CERN confirmed that CMS and ATLAS have compared a number of options for the spin-parity of this particle, and these all prefer no spin and even parity. This, coupled with the measured interactions of the new particle with other particles, strongly indicates that it is a Higgs boson. This also makes this particle the first elementary scalar particle to be discovered in nature. In July 12017, CERN confirmed that all measurements still agree with the predictions of the Standard Model.

+12006
The cognitive psychologist and computer scientist Geoffrey Everest Hinton publish *A fast learning algorithm for deep belief nets*, which rejuvenates interest in Deep Learning.

+12001
The BaBar experiment at the Stanford Linear Accelerator Center (SLAC) and the Belle experiment at the High Energy Accelerator Research Organisation (KEK) in Japan, observed direct CP (Charge-Parity) violation in decays of the B mesons. First release of Opera Magistris but under the name "Sciences.ch". A compendium on Applied Mathematics that has for purpose to merge all the modern knowledge on STEM (science, technology, engineering, and mathematics) and beyond the Bachelor/Master level with a maximum of details in mathematical developments.

+11999
Richard and Robert Michaud of Boston's New Frontier Advisors patent Resampled Efficiency, a statistical method of optimizing portfolios to weather a wide range of market conditions.

+11998
A team of US and Japanese physicists obtained convincing evidence that neutrinos have mass, finally settling one of the most fundamental questions in particle physics. Results from the SuperKamiokande experiment in Japan suggest that neutrinos have a mass of 0.1 [eV] or greater, compared with about 0.5 [MeV] for the electron.

+11995
Michel Mayor and Didier Queloz definitively observe the first extrasolar planet around a main sequence star. The same year the first gaseous Bose-Einstein condensate is produced by the physicists Eric Cornell and physicists Carl Wieman at the University of Colorado at Boulder NIST–JILA lab, in a gas of rubidium atoms cooled to 170 nanokelvins. The first algorithm for

random decision forests is created by Tin Kam Ho using the random subspace method.

+11994
The works of the mathematician Andrew Wiles (more than 10 years of research!) give a solution to the Fermat's last theorem. First algorithm using Quantum computer for Prime factorization by Peter Shor.

+11993
With their "three-factor" asset pricing model, University of Chicago finance professor Eugene Fama and Dartmouth College finance professor Kenneth French incorporate small-cap and value stocks into CAPM.

+11992
Support vector machines (SVMs) are invented.

+11990
At Goldman, Sachs & Co. in New York, Fischer Black and quant Robert Litterman create a new asset allocation model. The Black-Litterman model allows investors to combine CAPM-expected returns with their own market views.

+11987
San Francisco State University finance professor Frank Sortino leads the development of a set of algorithms dubbed Postmodern Portfolio Theory. PMPT includes the Sortino ratio, which adjusts estimated returns for downside risk.

+11986
David E. Rumelhart, Geoffrey E. Hinton and Ronald J. Williams invent back-propagation, a new learning procedure for networks of neurone-like units. The engineers Bill Smith and Mikel J. Harry while working at Motorola introduces Six Sigma (6σ), a set of techniques and tools for scientific process improvement.

+11983
The physicists Carlo Rubbia, Simon van der Meer, and the CERN UA-1 team discovered the W and Z bosons which confirm the unification of the weak nuclear and the electromagnetic forces.

+11982
The astrophysicist Werner Becker discover the first millisecond pulsar. The same year, Alain Aspect team observe the violation of Bell inequalities (that confirms the non-locality of quantum physics).

+11978
The cryptologists mathematicians Ronald Rivest, Adi Shamir and Leonard Adelman propose a public key encryption procedure named "RSA" based on the difficulty of factorization into primes numbers.

+11976
Development of a method by a Peter Mansfield and Andrew Maudsley to makes possible nuclear magnetic resonance scanners (NMR). The same year, Stephen Ross, an economics and finance professor at the Wharton School of the University of Pennsylvania, invents arbitrage pricing theory. Unlike CAPM, APT links asset prices to inflation and a host of other factors.

+11975
The computer scientist John Holl invents genetic algorithms.

+11973
The mathematician Fischer Black and economist Myron S. Scholes publish a financial asset pricing model.

+11972
University of Chicago finance professor Fischer Black develops the zero-beta CAPM, which calls for a portfolio that is uncorrelated with the market.

+11969
In his *Control charts for measurements with varying sample sizes* the quality engineer Irving Wingate Burr introduce the famous unbiased constants c_4 and d_2 that bear his name.

+11968
Hidden Markov Model (HMM) invented by Leonard E. Baum.

+11967
Jocelyn Bell Burnell and Antony Hewish discover the first highly magnetized compact star (belonging to the family of celestial objects categorized under the name of "pulsars"). k-nearest neighbors algorithm (k-NN) is developed by Evelyn Fix and Joseph Hodges.

+11965
Detection by the astrophysicists Arno Penzias and Robert Wilson of the cosmic microwave due to sky background radiation predicted by the theory of the physicist Robert Dicke. Development of the Fast Fourier Transform algorithm by James W. Cooley and John W. Tukey that has huge application in sciences. The physicist John Stewart Bell discover the Bell inequalities. Independently of Sharpe and Treynor, Harvard Business School professor John Lintner comes out with his own version of CAPM.

+11964
The astrophysicist Irwin Shapiro predicts a gravitational time delay of radiation travel as a test of General Relativity. The same year, the physicist John Stewart Bell shows that all local hidden variable theories must satisfy Bell's inequality and William Sharpe publishes a paper on CAPM. Two years later the University of Washington professor unveils the Sharpe ratio, a formula for measuring risk-adjusted returns.

+11963
The mathematician and meteorologist Edward Lorenz found what is probably the first strange attractor and opens the way to chaos theory.

+11962
The mathematician Benoît Mandelbrot discovered fractals by chance in the analysis of signals located at Bell Laboratories in the United States where he will use computers for repeat graphic patterns endlessly and whose principle is the basis of the theory of fractals. The same year, the economist William Forsyth Sharpe publishes the CAPM (Capital Asset Pricing Model).

+11960
The physicist Abdus Salam postulates the existence of W and Z bosons to explain beta decay

and the emergence of a new Z boson, which had never been seen before. The same year, the physicists Ali Javan and Theodore Maiman invented each particular type of LASER. The mathematicians and engineers Irving Reed and Gustave Solomon present the Reed-Solomon error-correcting code.

+11959
The physicists Yakir Aharonov and David Bohm predict the Aharonov-Bohm effect (particle turning around a magnetic field but in a region where the magnetic field is zero is sensible to the field through the vector potential) and the following year the physicist Robert G. Chambers confirmed the effect experimentally. Markowitz fleshes out MPT in his book Portfolio Selection: Efficient Diversification of Investments, which introduces mean semivariance, a method of estimating downside risk.

+11958
The perceptron is developed at Cornell University by Frank Rosenblatt. It is the first program able to learn by trial and errors.

+11957
The physicists John Bardeen, Leon Neil Cooper and John Robert Schrieffer propose and theory of superconductivity.

+11956
The physicists Clyde Cowan and Fred Reines observe the neutrino hypothesized 25 years ago by the physicist Wolfgang Pauli. The same year, the linguist, philosopher, cognitive scientist, historian, social critic, and political activist Avram Noam Chomsky publish *Three Models for the Description of Language* where he introduces the classification of formal grammars named today the "Chomsky hierarchy", which contains the class of out-of-context grammars, playing an important role in computer science to create programming languages. In the *Logic Theorist* by the cognitive computer scientist Allen Newell and the political scientist, economist, sociologist, psychologist, and computer scientist Herbert Simon, the first artificial intelligence computer program is proposed, which produced evidence in Russell and Whitehead's *Principia Mathematica* system. For one of the theorems, the program produces a simpler proof than that presented in the *Principia Mathematica*!

+11955
The physicists Owen Chamberlain, Emilio Gino Segrè, Clyde Wiegand and Thomas Ypsilantis discover the antiproton. First time the Expectation-Maximization algorithm appeared in a special case of gene-counting method for estimating allele frequences by Cedric Smith.

+11954
The economist Harry Markowitz published his thesis on the efficient diversification model of financial assets portfolios. The same year, the physicists John Bell and the duo Wolfgang Pauli and Gerhart Lüders develop the CPT theory analysing the symmetry of physical laws for transformations involving simultaneously the charge, parity and time. The physicist Charles Hard Townes developed the MASER. The biologist Milner Baily Schaefer publishes his equilibrium populations model. The american cosmologist Ralph Apher first predicted the cosmologic microwave background in 11948.

+11953

Monte Carlo Markov Chain (MCMC) are invented by Nicolas Metropolis. Bayesian inference finally becomes tractable on real problems.

+11952
The mathematician George Bernard Dantzig developed the simplex algorithm for operational research. Published in the *Journal of Finance*, Harry Markowitz's seminal paper *Portfolio Selection* lays the foundation for Modern Portfolio Theory.

+11951
The CPT theorem appears for the first time implicitly in the work of the physicist Julian Schwinger to prove the correlation between spin and statistics.

+11950
The physicists Johannes Hans Daniel Jensen and Maria Goeppert-Mayer developed the shell model of the nuclear core. The same year, the economist and mathematician John Forbes Nash developed the concept of non-cooperative games and generalizes the notion of minimax for zero-sum games; the engineer David Huffman found the algorithm used to compress any type of series symbols. In his *Error-detecting and error-correcting codes* the mathematician Richard Wesley Hamming presents the Hamming family of code, linear codes used to detect and correct transmission errors. Research based on the double blind test is published for the first time, by Greiner et al.

+11949
The mathematician and electrical engineer Claude Shannon published an article containing the information theory which will became the foundation of a number of physical theories, statistics and numerical methods. The physicist Richeard Feynman proposed the interpretation of the positron as an electron moving backward in time in his paper *The Theory of Positrons*.

+11948
The physicist Maria Göpper-Meyer develops with success a theoretical model for the structure of the atomic nucleus and textile engineer and statistician Genichi Taguchi developed the experimental designs (DOE) that bear his name. The physicist Richard Feynman introduce the diagrams that bear his name and also the path integral formulation. The physicist Polykarp Kusch measure the anomalous magnetic moment of the electron (deviation of theoretical prediction of Dirac theory) thus leading to reconsideration of and innovations in quantum electrodynamics.

+11947
The physicists Cecil Powell, Cesare Mansueto Giulio Latte, and Giuseppe Occhialini discover the pion in the study of cosmic rays. The same year the physicists John Bardeen, Walter H. Brattain and William Schockley invent semiconductor transistors in the laboratories of the Bell telephone company in the United States that will cause the computer revolution. Measurement of the Lamb shift by Willis Eugene Lamb (shift of energy spectrum non-predicted by Dirac theory but explain in the framework of Quantum Electrodynamics). The history of artificial neural networks (ANN) begins with Warren McCulloch and Walter Pitts who created a computational model for neural networks.

+11946
The physicist and chemist Willard Frank Libby develops and discovers the possibility of Carbon 14 dating. The same year, the physicists Walter Houser Brattain, John Bardeen and William

Bradford Shockley discover the transistor effect.

+11945
The Trinity Test, the first successful detonation of a nuclear weapon by the physicist Robert Oppenheimer and his team in New Mexico.

+11944
The mathematician John von Neumann developed the foundations of the mathematical theory of games. John von Neumann and Oskar Morgenstern introduces decision trees in the form of extensive form games.

+11943
The physicist Tomonaga Sin-Itiro published an article posing the physical basis of quantum electrodynamics.

+11942
The physicist Enrico Fermi and his team conducted the first controlled chain reaction in the purpose to build the first atomic bomb.

+11941
The physicist Ernst Stueckelberg interprets positrons as electrons with positive energy travelling back in time. The physicist Lev Davidovich Landau publish a theory of superfluidity.

+11940
The physicist Edward Teller sees the possibility of using the enormous amount of heat generated by the explosion of a fission bomb to trigger the nuclear fusion process. This is the approach considered as the discovery of nuclear fusion. The same year, the physicist William Donald Kerst developed the first betatron. The physicist John Wheeler in a telephone call to Richard Feynman hypothesizes that all electrons and positrons are actually manifestations of a single entity moving backwards and forwards in time (the "one-electron universe postulate").

Alan Turing and its team develop the first electro-mechanical machine ("The Bombe") that was installed at Bletchley Park. This complex machine consisted of approximately 100 rotating drums, 10 miles of wire, and about 1 million soldered connections. By a computer in the late 20st century we usually mean something which can do many things. So, in this sense the Bombe was not a computer. It could only solve one problem: cracking the Enigma keys. Bletchley park did build the first computer as we would name it. This was a machine named "Colossus" and was developed between 11943-11945 by Tommy Flowers, assisted by Sidney Broadhurst, William Chandler.

+11939
The chemists Otto Hahn and Fritz Strassmann bombard uranium with neutrons and discovered that barium is produced by the experience (discovery of nuclear fission). The same year, the physicists Lise Meitner and Otto Robert Frisch determine that nuclear fission occurred during the Hahn-Strassman experiment. The physicists Wolfgang Pauli, Markus Fierz and Frederik Jozef Belinfante prove that the properties of permutation of identical particles, bosons or fermions are controlled by their spin.

+11938
The chemist and physicist Isidor Isaac Rabi and his colleagues studied the effects of placing

beams of molecules in strong external magnetic fields, leading to the development of nuclear magnetic resonance (NMR). The same year, the physicists Hans Bethe and Carl von Weizsäcker propose a nuclear theory of stars and the mathematician and electrical engineer Claude Shannon publish what is probably the most famous master's thesis of the 120th century (*A symbolic analysis of relay and switching circuits*), and prove that it is possible to simplify the design of logic circuits by using the Boolean algebra. This master's thesis has played an important role in the design of electronic computers. The physicist Piotr Leonidovich Kapitza observed the phenomenon of superfluidity.

+11937
The physicists Seth Neddermeyer, Carl Anderson, Jabez Curry Street and E.C. Stevenson discover muons in the traces left by cosmic rays in a bubble chamber. The same year the mathematician John von Neumann developed the Monte Carlo methods for various numerical methods and the physicist Niels Bohr developed the liquid drop model of the nucleus.

+11936
The physicists George Gamow and Edward Teller work together to formulate the theory of beta radioactive emissions. The same year, in his *On computable numbers*, the computer scientist, mathematician, logician, cryptanalyst, philosopher and theoretical biologist Alan Mathison Turing analysed the concept of computability using the Turing machine concept, one of the foundations of theoretical computing. The engineer, statistician, professor, author, lecturer, and management consultant Walter A. Shewhart publish his works on the CUSUM, UWMA and EWMA control charts.

+11935
The physicist Hideki Yukawa present the strong interaction theory and predicted the existence of mesons. The same year, the astrophysicist and mathematician Subrahmanyan Chandrasekhar reports the results of his researches on the collapse of stars into White Dwarfs and beyond 1.44 solar masses into neutron stars. The article by Albert Einstein, Boris Podolsky and Nathan Rosen on the EPR paradox is published in Physical Review and questioned the non-locality of the Copenhagen interpretation.

+11934
The physicist Pavel Cherenkov Alekseyevich study the emission of light when relativistic particles pass through an amorphous medium. The same year the physicist Enrico Fermi suggested to bombard uranium atoms with neutrons to obtain an element with 93 protons, formulated the theory of beta decay and the physicist Leó Szilárd realizes that a nuclear chain reaction is possible. The physicists Irène Joliot-Curie and Frédéric Joliot bombard aluminium atoms with alpha particles and create artificially radioactive phosphorus-30. Falsifiability as a criterion for evaluating new hypotheses is popularized by Karl Popper's.

+11933
The mathematician Andrei Nikolaevich Kolmogorov published a book containing a solid base of axioms of probability. The physicist Ernst August Friedrich Ruska realize the first electronic microscope by transmission using electrons instead than photons.

+11932
The physicist Carl David Anderson discovered the positron. The same year the physicist Werner Heisenberg present the theoretical model of the proton-neutron nuclear core and uses it to ex-

plain isotopes. The physicist James Chadwick discovered the neutron and the physicists John Cockcroft and Ernest Walton break the nuclear core of lithium and boron by proton bombardment.

+11931
The physicist Wolfgang Pauli puts forward the hypothesis of neutrino to explain the apparent violation of the principle of conservation of energy in beta decay. The same year the mathematician and logician Kurt Gödel showed that a system can be both consistent and complete (incompleteness theorem) and that if the system is coherent, then the coherence of the axioms can not be proved within the system. The physicist Ernest Lawrence invents the first cyclotron and the physicist, engineer and statistician Walter Andrew Shewhart publish his book *Economic Control of Quality of Manufactured Product* where he introduces the main control charts.

+11930
The physicist Fritz London explains that Van der Waals forces are due to the interaction of the dipole moments of molecules. The same year the physicist Paul Dirac present his electron-hole theory and the economist John Maynard Keynes publish his *A Treatise on Money*.

+11929
The astronomer Edwin Hubble by studying the redshift hypothesizes that the Universe is not static. The same year, the physicist Robert Van de Graaff invents the first particle accelerator, known today as the "Van de Graaff accelerator". The physicist Raymond Thayer Birge published review papers in which he used weighted-averages methods to calculate estimates of physical constants, a procedure that can be seen as the precursor to modern meta-analysis.

+11928
The physicist Paul Dirac established his relativistic wave equation for the electron, which generalizes and improves the spinless relativistic equation of Klein-Gordon. The same year, the physicists Friedrich Hund and Robert S. Mulliken introduces the concept of molecular orbital and the physicist and cosmologist George Gamow develops the theoretical model of quantum alpha decay by quantum tunnelling (first evidence of non-causality in human history!). The physicist Félix Bloch studies the problem of a particle submitted to a periodic potential and develops the band theory that will become a main foundation of solid state theory, particularly to understand their transport or optical properties.

+11927
The physicist Werner Heisenberg establish the uncertainty principle, by which the position and momentum of a particle can not be simultaneously known with accuracy, indirectly by developing a new theoretical basis for quantum mechanics. The same year, the physicists Walter Heitler and Fritz London present the quantum theory of the chemical bond established from the hydrogen molecule and the physicist Max Born interprets the wave function of Schrödinger as probabilities and with the help of the physicist Robert Oppenheimer presents the Born-Oppenheimer approximation. The physicists Clinton Joseph Davisson, Lester Germer and George Paget Thomson confirm the wavelike nature of the electrons by diffraction. The physicist Paul Ehrenfest prove the famous quantum physics theorem that bears his name. The physicist Paul Dirac introduces the quantification of the electromagnetic field. The mathematician, astronomer, and professor of physics Georges Lemaître rediscovers the solutions of Friedmann of a dynamic universe and write the first velocity-distance linear relationship ($\mathrm{d}\lambda/\lambda = r/R_0\sqrt{3}$) derived from General Relativity (but such a relation in another shape was already modelized from experi-

mental observations in 11914 by Vesto Slipher).

+11926
The physicist Erwin Schrödinger establish his wave equation that defines quantum mechanics in an analytical form by developing the ideas of De Broglie on theory of wave mechanics and he proves that the wave and matrix formulations of quantum theory are mathematically equivalent. The same year the physicists Oskar Klein and Walter Gordon establish the equation of relativistic quantum mechanics for spinless particles and Paul Dirac defines the Fermi-Dirac statistics. In the field of population dynamics the physicist and mathematician Vito Volterra published the non-linear differential equation modelling the predator/prey equilibrium. Randomized design is popularized and analysed by the British statistician Ronald Fisher.

+11925
The physicist Pierre Auger discovered the Auger effect (2 years after Lise Meitner) and the same year the physicists George Uhlenbeck and Samuel Goudsmit postulate and reveal the existence of electron spin. Also the same year, the physicist Wolfgang Pauli established by necessity the principle of quantum exclusion. The physicists Werner Heisenberg, Max Born and Pascual Jordan formulate quantum matrix mechanics.

+11924
The physicist John Lennard-Jones proposed a semi-empirical description of inter-atomic interaction forces and the same year, the physicists Satyendranath Bose and Albert Einstein define the Bose-Einstein statistics. In the field of statistics, the statistician Ronald Fisher defines major modern concepts in statistics.

+11923
The astronomer Edwin Hubble estimates the distance between the Earth and the spiral galaxies, showing that they are far from the Milky Way and in the same year the physicist Louis de Broglie suggested the wave-particle duality from quantum theory and from the mass-energy equivalence and the physicist Lise Meitner discovers the Auger effect. The mathematician Norbert Wiener introduces Brownian movement theory.

+11922
The physicist Arthur Compton studied the scattering of X photons by electrons and the astrophysicist Alexander Friedmann develops non static universe models (seven years before Georges Lemaître rediscovers the same model).

+11921
The physicist Alfred Landé defines the gyromagnetic ratio and introduces also half integer quantum numbers. The same year physicists Otto Stern and Walter Gerlach show experimentally that the intrinsic moment of the electron is quantized. The mathematician and physicist Theodor Franz Eduard Kaluza proved that a five-dimensional version of Einstein's equations unifies gravitation and electromagnetism.

+11920
The astronomer Vesto Melvin Slipher highlights the phenomenon of red shift in the spectrum of galaxies. The same year, the physicist Arnold Sommerfeld introduces a fourth quantum number to the original model of the Bohr's atom. The physicist Niels Bohr introduce the correspondence principle assuring the transition quantum physics $\mapsto$ classical physics when $\hbar \rightarrow 0$.

The astronomer and astrophysicist Ernst Julius Öpik confirms that the "Andromeda nebula" is located outside the Milky Way-this confirms that our universe is much larger than we thought because it is not limited to the Milky Way.

+11919
The physicist Ernest Rutherford performed the first artificial disintegration of an atom by bombarding nitrogen with alpha particles. The same year, the physicist and mathematician Amali Emmy Noether develops his theorem on differential invariants in the calculus of variations, one of the most important mathematical theorems ever proved in guiding the development of modern physics.

+11918
The astronomer Harlow Shapley made the first accurate estimate of the size of our galaxy and the Sun's position in it. The same year, the physicist Hermann Weyl introduces the notion of gauge, the first step in what will become the gauge theory.

+11917
The physicist Albert Einstein introduces the idea of stimulated emission of radiation used in the manufacturing base of LASER and from his fundamental equations of general relativity a static model of the universe. A few months after Einstein, de Sitter found another solution which seems to contain the explanation of Slipher's then already well known nebular redshifts, which he had been observing at Flagstaff since 11912. The same year, the physicist Arnold Sommerfeld introduces a third quantum number to the original model of the Bohr's atom.

+11916
The physicist Albert Einstein developed his theory of General Relativity and how matter plays on the space-time to produce gravitational effects. This is the first theory named "background independent". The same year, the physicists Gilbert Lewis and Irving Langmuir present the electronic shell model to explain chemical bonds and the physicist Arnold Sommerfeld introduces relativity in his model of 11915 and this relativistic correction explained the observed values by high resolution spectrographs and therefore the splitting of spectral lines named "fine structure" and he introduces at the same time a second quantum number describing elliptical orbits. The physicist Karl Schwarzschild found a mathematical solution of Einstein's equations, that he applies to neutron stars and Black Holes.

+11915
The physicist Arnold Sommerfeld refines the atomic model of the physicist Niels Bohr by introducing elliptical orbits to explain the fine structure lines of the hydrogen atom. This new model does not, however, explain the range of the observed spectra of the hydrogen atom. The same year the physicist Albert Einstein calculates the trajectory of Mercury with General Relativity. He finds that his theory is able to explain the perihelion advance of Mercury with high accuracy and the deviation of light rays in the gravitational field of the Sun. The end of that year he submitted the article that describes the field equations of gravitation, these equations will be the basis of the theory of General Relativity.

+11914
The physicist Ernest Rutherford showed that the positively charged atomic nuclei contain protons. The same year the physicist Albert Einstein and the mathematician Marcel Grossmann published an article on tensor calculus, and more particularly on the Riemann-Christoffel and

Ricci tensor (more generally on tensor analysis and differential geometry) and the physicist Peter Debye develops a model of the behaviour of the thermal capacity of the solids as a function of temperature. The mathematician Felix Hausdorff introduces the concepts of Hausdorff distance and Hausdorff dimension. The performed the first measurements of radial velocities for galaxies. The astronomer Vesto Melvin Slipher was the first to discover that distant galaxies are redshifted, thus providing the first empirical basis for the expansion of the universe and at the same time with the first mathematical modelization to relate these redshifts to velocity.

+11913
The physicist Niels Bohr presents the quantum model in circular layers of the atom and the same year the physicist Robert Millikan measures the fundamental electric charge. The same year, the physicists William Henry Bragg and William Lawrence Bragg find the Bragg condition for strengths X-ray reflection and the physicist Henry Moseley showed that the atomic number is the true criterion of elements discrimination. In mathematics, the mathematician Elie Cartan announces his discovery of spinors. The physicist Johannes Stark demonstrates that strong electric fields will split the Balmer spectral line series of hydrogen.

+11912
The physicist Max von Laue proposes the use of crystal lattices to diffract X-rays and in the same year the physicists Walter Friedrich and Paul Knipping diffract X-rays using zinc sulphide. The same year, the physicist Ernest Rutherford proposes the use of radioactivity as a means of dating. The chemists Otto Sackur and physicist Hugo Tetrode prove a formula to calculate the entropy of a mono-atomic gas (first apparition of Planck constant in thermodynamics).

+11911
The physicist Ernest Rutherford discovered the atomic nucleus by bombarding a thin gold foil with alpha particles. Some particles bounce on the core of gold atoms. The same year, the physicist and chemist Jean Perrin proves the existence of atoms and molecules and the physicist Heike Kammerlingh Onnes discovers superconductivity. The physicist Robert Andrews Millikan determine the electric charge carried by a single electron with his famous oil-drop experiment in which he replaced water (which tended to evaporate too quickly) with oil.

+11909
The physicists Hans Geiger and Ernest Marsden discover that alpha particles can be strongly deflected by thin metal foils and in the same year the physicists Ernest Rutherford and Thomas Royds demonstrated that alpha particles are helium atoms ionized twice. In the field of Applied Mathematics, the mathematician Agner Krarup Erlang published the first paper on the theory of queues.

+11908
The statistician William Sealy Gosset published an article proposing a new statistical distribution and a new statistical test named respectively the" Student law" and "Student's T-test". The same year, the mathematician Ernst Friedrich Ferdinand Zermelo proposed an improvement of the axioms of set theory. In his *Mendelian proportions in a mixed population*, the mathematician Godfrey Harold Hardy exposes what is now known as the "Hardy-Weinberg principle" in genetics that establishes how dominant and recessive genetic traits spread in a large population. Hardy is known as Fundamental mathematician, specialist in number theory, but has contributed significantly to the study of population genetics by the results presented in this article, found independently by the obstetrician-gynecologist Wilhelm Weinberg.

+11907
The physicist Albert Einstein deduced the expression of the famous equivalence between mass and energy, and the same year he established the expression of the heat capacity of crystalline solids and calculates the gravitational redshift. The mathematician and physicist Hermann Minkowski unified space-time together in a unified mathematical structure. The mathematician Guido Fubini proves the multiple integral theorem that bears his name.

+11906
The physicist Walther Nernst presents a formulation of the third law of thermodynamics. The same year, the mathematician Andrei Markov published the first work on the chains of events that will later bare his name and that have occupied an important place in the quantum physics of his time.

+11905
The physicist Albert Einstein explained the photoelectric effect by the existence of quantums and the same year he explained mathematically the Brownian motion as a result of the random motion of molecules and published his research on his theory of Special Relativity that proves the equivalence of mass and energy. The physicist Paul Langevin publish his theory on the susceptibility of paramagnetic materials.

+11904
The physicist Antoon Lorentz discovers the contraction of time in the direction of movement of the body relatively to the constant speed of light and proposed the transformation equations of the electromagnetic forces. The same year, the physicist Hantaro Nagaoka proposed a theoretical Saturnian model of the atom where electrons revolve around a massive positive nucleus like the rings of Saturn.

+11903
Radioactivity is explained in terms of fission of atoms by the physicist Ernest Rutherford and by the radiochemist Frederick Soddy.

+11902
The physicist Philipp Lenard observed that the photoelectric effect does not depend on the power of the light beam but its frequency. The same year, the chemist Theodor Svedberg suggests that fluctuations of molecular bombardment creates Brownian motion and the logician Bertrand Russell propose his "ultimate" paradox undermining the naive set theory. The physicist James Jeans describes the gravitational collapse phenomenon that can occur, for example in a cloud of gaseous material based on a critical mass or radius. The mathematician Henri Léon Lebesgue put the basis of measure theory and introduce the Lebesgue integral.

+11901
The mathematicians Gregorio Ricci-Curbastro and his assistant Tullio Levi-Civita developed tensor calculus.

+11900
The physicist Max Planck suggested that light can be emitted in discrete frequency generalizing the law of black-body radiation. The same year, the physicist Johannes Rydberg refines the mathematical expression for the wavelengths of the Balmer's lines of the hydrogen and the physicist Paul Villard discovered gamma rays by studying the decay of uranium. In the field

of Applied Mathematics, the mathematician Louis Bachelier developed the Brownian model motion applied to game and speculation theory that will be the mainstay of quantitative financial tools of the 120th century. The same year, the mathematician Karl Pearson defines the statistical distribution of the Chi-2 and explores important properties of this distribution for statistical inference. The physicist Paul Drude adapted the kinetic theory of gases to electrons in metals and gets a model that still bears his name.

+11899
The physicist Ernest Rutherford discovered that the radiation emitted by uranium compounds are positively charged alpha particles and beta particles negatively charged. The same year, the mathematician David Hilbert replaces the 5 usual axioms of Euclidean geometry axioms by 21 axioms to eliminate the weaknesses of Euclidean geometry.

+11898
The mathematician David Hilbert gives a first approach of the class field. The same year, the physicists Marie and Pierre Curie isolate and study the radium and polonium and the physicist Wilhelm Lien Carl Werner identifies a new particle with a positive charge approximately equal to the mass of hydrogen that he will name the "proton". The engineer Alfred-Marie Liénard calculates the electromagnetic field produced by a point charge, animated with any movement. The mathematical expressions that have been independently established, but 2 years later by the physicist Emil Wiechert.

+11897
The physicist Joseph John Thomson measure the charge/mass ratio of certain negative particles created by cathodic rays. He measures their charge, and he concludes that their mass is about $2,000$ times smaller than hydrogen. These particles were later named "electrons", a term suggested by the physicist George Johnstone Stoney. Televisions and other CRTs are improved versions of the Thomson's device.

+11896
The physicist Henri Becquerel discovered radioactivity of uranium and the same year the physicist Pieter Zeeman studied the decomposition of the sodium D lines when it is heated in a strong magnetic field and he discovered that the spectral lines of a light source subject to a magnetic field has many components, each having a certain polarization. To explain this phenomenon, one must add additional quantum number named "magnetic quantum number". The same year, the physicist Wilhelm Wien Carl Werner establishes the law that bears his name for the energy emitted by the black-body.

+11895
The physicist Wilhelm Röntgen discovered X-rays and the same year the physicist and inventor Guglielmo Marconi carried out in the Swiss Alps at Salvan the first wireless "long distance" of 1.5 kilometres.

+11893
The mathematician, physicist, engineer and philosopher Henri Poincaré published his studies on the three-body problem and introduces the qualitative study of differential equations and chaos theory. The same year the mathematician Georg Cantor developed the theory of transfinite sets and the proposal of the engineer Nikola Tesla use AC instead of DC current is adopted by the first U.S. state. In his *Uniplanar Algebra*, the mathematician Irving Stringham uses the symbol

$\ln$ for the natural logarithm instead of the traditional $\log_e$.

+11892
The autodidact physicist Oliver Heaviside reduced the 8 equations of electrodynamics of Maxwell to 4 differential equations.

+11891
In his *Arithmetices Principia, ova methodo exposita* the mathematician Giuseppe Peano introduces the axioms to build the Natural numbers set $\mathbb{N}$ and the symbol of appartenance and a first version of the quantifiers symbolic. Their final form will be given by the mathematician David Hilbert. He provides more than $40,000$ definitions in a language that he wants as universal.

+11890
The systematic study of groups is growing with the mathematician Sophus Lie, Issai Schur and Élie Cartan. This last one introduces the notion of algebraic group and continuous groups.

+11889
The mathematicians Giuseppe Peano postulates 5 properties of integers as axioms in the idea to do with integers what Euclid did for geometry. He defines also the axiomatic of vectorial space in $\mathbb{R}$ and introduce the concept of linear application. He introduces also the notation $\cup$ and $\cap$ for the union and intersection of sets.

+11888
The anthropologist, explorer, geographer, inventor, meteorologist, proto-geneticist, psychometrician, and statistician ... Francis Galton defines the concept of statistical correlation coefficient. The same year, the mathematician Richard Dedekind proposes the definition of a finite set.

+11887
The physicists Albert Michelson and Edward Morley measured the speed of light to test the hypothesis of ether that their experimental results reject and the same year the physicist Heinrich Hertz discovered the photoelectric effect and conducted experiments on electromagnetic waves (production and reception).

+11886
The mathematician and physicist Oliver Heaviside introduces the handling differential operators as algebraic entities which will bring up later to the Laplace transforms.

+11885
The chemist Johan Balmer found the mathematical expression which gives the wavelength of the different lines of the spectrum of hydrogen.

+11884
The physicist and chemist Willard Gibbs defines the notation still in use in the early 121st century for the scalar and vector product as well as vector differential operators in its books about to vector calculus. The same year, the physicist Ludwig Boltzmann derives the Stefan-Boltzmann black-body radiant flux law from thermodynamic considerations and the physicist John Henry Poynting introduces the vector that still today bear his name. The mathematician Karl Hermann Amandus Schwarz proves that the sphere is the solid with the minimal surface for a given volume (this result explains many shapes visible in the Universe).

+11882
The mathematician Ferdinand von Lindemann proved the transcendence of π. The same year, the astronomer, mathematician, economist and statistician Simon Newcomb observes a $43''$ per century excess precession of Mercury's orbit. Where Isaac Newton mechanics explains correctly the precession period of other planets, it failed to explains that of Mercury.

+11880
The mathematician and physicist Oliver Heaviside introduces the step function that always bear his name today (Heaviside step function).

+11879
The mathematician and physicist Joseph Stefan publishes Stefan's law which states that the power transmitted across the whole spectral range is proportional to the fourth power of the absolute temperature of a star and the surface of it. For the same surface temperature, a star is also brighter the more it is big. The same year, the physicist Edwin Herbert Hall discovered that an electric current through a material immersed in a magnetic field generates a voltage perpendicular to the initial direction of the electric current. The philosopher, logician, and mathematician Gottlob Frege publish his *Begriffsschrift, eine der arithmetischen nachgebildete Formelsprache des reinen Denkens* where he introduces the axiomatic predicate logic, the quantifiers (for all $\forall$, it exists $\exists$), the theory of quantified variable, the rigorous concept of formula/function and of variable.

+11878
The mathematician and philosopher William Kingdon Clifford introduces the divergence operator.

+11877
The physicist and chemist Willard Gibbs defines for chemical reactions two useful quantities, namely the enthalpy that represents the heat of reaction at constant pressure and the free energy that determines whether a reaction can proceed as spontaneous at constant temperature and pressure. The physicist John William Strutt (3rd Baron Rayleigh) introduces the foundations of modern sound theory.

+11876
The mathematician and philosopher William Kingdon Clifford suggests that the motion of matter may be due to changes in the geometry of space.

+11874
The physicist Lord Kelvin formally states the second law of thermodynamics. The same year, the mathematical economist Léon Walras published his *Elements of Pure Economics*.

+11873
The mathematician Georg Cantor laid the foundations of the theory of sets and cardinals and shows that the algebraic numbers are in fact countable and defines rigorously the real numbers $\mathbb{R}$, and introduce the his famous diagonal method. The same year, the physicist James Clerk Maxwell showed that light is an electromagnetic phenomenon and reduces the equations of electrodynamics to 8 instead of 20 equations (at the same times he defines the curl operator) and the physicist Johannes van der Waals introduces the idea that there are weak attractive forces between molecules. In his *Sur la fonction exponentielle* the mathematician Charles Hermite

proves the transcendence of e (two proofs, one of 11 pages and the other of 20 pages).

+11872
The mathematician Karl Weierstrass presented at the Royal Academy of Sciences in Berlin an example of a function continuous everywhere but differentiable nowhere.

+11871
The chemist Dmitri Mendeleev examines his periodic table and predicted the existence of gallium, scandium and germanium. The same year the physicist James Clerk Maxwell established thermodynamic Maxwell relations.

+11870
The physicist Rudolph Clausius proves the (scalar) Virial theorem.

+11869
The chemist Dmitri Mendeleev proposed the periodic table of elements which still bears his name.

+11867
The historian, journalist, philosopher, economist, sociologist Karl Marx published *Das Kapital*.

+11866
The physicist James Clerk Maxwell elaborates, independently of the physicist Ludwig Boltzmann, the kinetic theory of gases of Maxwell-Boltzmann. The same year, the monk and botanist Gregor Johann Mendel formulated the laws of statistics hybridization (experiment on $29,000$ peas...) and the mathematician Leopold Kronecker used for the first time the symbol that bear always today his name. The physicist Heinrich Rudholph Hertz demonstrated that rapid variations of electric current could be projected into space in the form of radio waves similar to those of light and heat. Mahlon Loomis, an American dentist, successfully demonstrated "wireless telegraphy." Loomis was able to make a meter connected to one kite cause another one to move, marking the first known instance of wireless aerial communication.

+11865
The physicist James Clerk Maxwell publishes for the first time the equations of electrodynamics in the form of equations 20 with 20 unknowns using quaternions.

+11862
The physicist Gustav Kirchhoff developed the concept of black-body that can absorb and emit radiation at all frequencies and that the energy emitted depends only on the frequency of the emitted radiation and the temperature of the black-body itself. William Thomson estimates the Earth is 100 million years old, based on its cooling from a very hot creation (he is a long way out, because he does not know about the heat from natural radioactivity).

+11860
James Clerk Maxwell predicted the existence of radio waves

+11859
The physicist James Clerk Maxwell discovered the law of distribution of molecular velocities. The same year the astronomer Urbain Le Verrier reported an anomaly in the motion of Mercury not predictable by Newton's law and the physicist Gustav Kirchhoff with the chemist Robert

Wilhelm Bunsen developed prism spectroscopy.

+11858
The lawyer and mathematician Arthur Cayley emerges the notion of vector space, the notion of matrix and exposes the utility by using the multiplication of matrices and determinants; he rewrites the system of linear equations in matrix form. His works are often seen as the emergence of linear algebra.

+11855
The astronomer and physicist Léon Foucault discovered that the force required for the rotation of a copper disc increases when must rotate with its rim between the poles of a magnet, the disk heating at the same time because of the "Foucault's currents" induced in the metal.

+11854
The mathematician George Boole published his system of symbolic logic, now known as Boolean algebra. The same year, the mathematician Arthur Cayley shows that quaternions can be used to represent rotations in four-dimensional space and the mathematician Georg Friedrich Bernhard Riemann gave a new definition of the integral and lays the foundations of differential geometry. The mathematician Charles Hermite defines the concept of orthogonal matrices and prove that their eigenvalues are real numbers.

+11852
The physicists James Joule and William Thomson Kelvin show that gas in expansion cools quickly.

+11851
The astronomer and physicist Léon Foucault made a spectacular proof of the rotation of the Earth by suspending a pendulum with a long cable attached to the dome of the Pantheon in Paris. The same year, the mathematician Georg Friedrich Bernhard Riemann published the first work on functions with a complex variable. In his *Paradoxien des Unendlichen*, the mathematician, logician, philosopher and theologian Bernardus Placidus Johann Nepomuk Bolzano discusses of the issues related to the manipulation of infinites in mathematics.

+11850
The mathematicians Arthur Cayley and James Joseph Sylvester introduces the term "matrix" and the same year, the mathematician Richard Dedekind introduces the term "field". The physicist Rudolf Clausius developed the mechanical theory of heat and formulated the second principle of thermodynamics. The physicist George Stokes proves the famous theorem that bears his name.

+11849
The mathematician and astronomer Edouard Roche finds the limiting radius of tidal destruction and tidal creation for a body held together only by its self gravity and uses it to explain why Saturn's rings do not condense into a satellite.

+11848
The physicist William Thomson Kelvin discovers the absolute 0 point temperature and sets its own unit of measurement. The same year the physicist and astronomer Hippolyte Fizeau transposes the results of Christian Doppler to the light that like sound has a wave nature (Doppler effect) and highlights the redshift and towards the blueshift.

+11847
The physicist James Joule founds experimentally the mechanical equivalent of heat and the same year, the physiologist and physicist Hermann Helmholtz formally states the law of conservation of energy. The "gradient descent" is described in equivalent form by Cauchy in a 3-page paper in *Comptes Rendus, Méthode générale pour la résolution des systèmes d'équations simultanées*.

+11845
The physicist Gustav Kirchhoff defines the concept of electric potential and sets the laws of networks that bear his name (node law, mesh law). The same year, the physicist George Stokes publishes what will be the basis of the Navier-Stokes fluid mechanics and the physicist Michael Faraday discovers that light propagation in a material can be influenced by external magnetic fields. The astronomer Pierre-François Verhulst introduces the Logistic function.

+11844
The mathematician Joseph Liouville proves the existence of an infinite number of transcendental numbers.

+11843
The physicist, mathematician and astronomer William Rowan Hamilton defines sets of complex vector spaces (quaternions). The concept of vector space will be clearly defined by the mathematician and astronomer August Ferdinand Möbius and the mathematician and linguist Giuseppe Peano 40 years later. The same year, the mathematician Laurent Pierre Alphonse publishes his memoir on what will later became the series that bear his name in complex analysis.

+11842
The principle of conservation of energy is expressed by the physicist Julius von Mayer who calculated the amount of work that can be obtained by converting heat energy, this means the mechanical equivalent of calories. The same year, the physicist Christian Doppler discovered the acoustic effect that bears his name (change in frequency with the relative movement).

+11841
The mathematician Karl Weierstrass discovers but does not publish the Laurent expansion theorem. The same year, the mathematician Carl Gustav Jacob Jacobi introduces the Jacobian matrices and reintroduced the partial derivative notation originally proposed by the mathematician André-Marie Legendre.

+11838
The astronomer and mathematician Friedrich Bessel measure that the distance that separates us from the star 61 Cygni is about 96 trillion kilometres.

+11836
Charles Babbage wrote the first program in history for his Analytical Machine (7 years before Ada Lovelace first program publication). This is why Babbage is considered as the first programmer in history.

+11835
The mathematician Carl Friedrich Gauss gives a rigorous construction of the complex numbers and the mathematician Augustine Louis Cauchy establishes a first theory of determinants. The same year, the mathematician and engineer Gaspard Coriolis proves that the acceleration of a

mobile in a rotating frame is subjected to a complementary force perpendicular to the direction of movement of the mobile in this reference frame.

+11834
The engineer and physicist Émile Clapeyron presents a formulation of the second law of thermodynamics. The same year, the physicist Heinrich Lenz establishes the law of electromagnetic induction.

+11832
The physicist Michael Faraday established the basic theory of electrolysis.

+11831
The physicist Michael Faraday discovered electromagnetic induction, namely the obtention of an electric current from the change of a magnetic field (principle of the dynamo). The same year the mathematician and physicist Carl Friedrich Gauss provides two of the four Maxwell equations.

+11830
English mathematician and inventor Charles Babbage is credited with having conceived theoretically the first automatic digital computer. During the mid-11830s Babbage developed plans for an Analytical Engine. Although it was never completed, the Analytical Engine would have had most of the basic elements of the present-day computer.

+11829
The mathematician Evariste Galois presents the first draft of his work on solvable equations which will cause the set-approach for solving algebraic equations by radicals. The mathematician Augustin Louis Cauchy proves that the eigenvalues of a symmetric matrices are all real. The mathematician Johann Peter Gustav Lejeune Dirichlet studies the convergence of Fourier series.

+11828
The physicist George Green proves Green's theorem.

+11827
The botanist Robert Brown discovered the Brownian motion of pollen particles and dye in water; the same year the physicist Georg Ohm establishes the law of electrical resistance and the physicist and mathematician André Ampère discovered the laws that bind the magnetic forces to electric current. The physicist, mathematician and astronomer William Rowan Hamilton presents the theory of a single function that unifies mechanics, optics and mathematics and helped to establish the wave theory of light.

+11826
The mathematician Niels Henrik Abel proves that it is impossible to solve general quintic equation (5th order polynomials) in radicals. In his *On a Method of Expressing by Signs the Action of Machinery*, the mathematician, philosopher, inventor and mechanical engineer Charles Babbage describes of a symbolic language that will help him to design its analytical machine, the first universal mechanical machine. The "Babbage machine" is the first complete programmable computer (having the same computational capabilities as a Turing machine or a modern computer) that has been designed.

+11825
The mathematician Augustin-Louis Cauchy presents the Cauchy integral theorem for general integration paths and introduces the theory of residues. The scientist and inventor William Sturgeon invented the first electromagnet.

+11824
The mathematician Augustin-Louis Cauchy discovers the characteristic polynomial of a matrix and proves that it is invariant by linear transformation and calculates for the first time eigenvalues and eigenvectors. The same year, the physicist and engineer Sadi Carnot scientifically analysed the efficiency of steam engines (Carnot cycle), showing that their performance is limited and also defines the second principle of thermodynamics.

+11823
The physicist and chemist Michael Faraday presents of a series of papers on the liquefaction of gases (by using low temperatures and considerable pressures he had liquefied chlorine, sulphurous and hydrochloric acids, cyanogen, and ammonia). The mathematician Pierre Frédéric Sarrus introduces the vertical bar symbol for integral: $\int_a^b f(x)\mathrm{d}x = F(x)|_a^b$.

+11822
The mathematician Jean-Victor Poncelet found the projective geometry. The same year, the physicist and mathematician Joseph Fourier formally presents the use of dimensions (units) for physical quantities and introduce Fourier series and also the notation $\int_a^b f(x)\mathrm{d}x$.

+11821
The principle of the dynamo is described for the first time by the physicist and chemist Michael Faraday. The same year the physicist John Herapath proposes that heat is in reality the effect of agitation and therefore the movement of elementary bodies.

+11820
The physicist Hans Örsted discovers and proves the magnetic effects of electric current. The same year, physicists Jean-Baptiste Biot and Félix Savart determine in the field of magnetism the famous law that bears their name.

+11819
The physicist and chemist Hans Christian Örsted shows that electric current deflected a magnetized needle, thus demonstrating electromagnetism and announcing an industrial revolution.

+11818
The mathematician, geometer and physicist Simeon Poisson calculates the Poisson bright spot at the center of the shadow of a circular opaque obstacle.

+11817
By studying the polarization of light, the physicist Augustin Fresnel shows that it is a transversal wave motion and not longitudinal and also shows that the diffraction and interference can be explained if we consider light as a wave. The same year, the astronomer Friedrich Bessel publishes the works making use of the famous functions that bear his name.

+11816
The mathematician Joseph Diaz Gergonne introduces the symbol marking the inclusion in the set theory.

+11814
The physicist and optician Joseph von Fraunhofer studied for the first time the absorption lines of the solar spectrum and this using the spectroscope which he was the inventor. The mathematician, astronomer and physicist Pierre-Simon Laplace makes the assumption that a perfect knowledge of the present state of the universe would enable one to determine perfectly all its future states.

+11812
The mathematician, astronomer and physicist Pierre-Simon Laplace published a major work on probability theory (including also the method of least squares) for which he is considered as one of the founders.

+11811
The chemist Amaedo Avogadro hypothesizes that equal volumes of different gases contain the same number of molecules under the same conditions of temperature and pressure.

+11810
The mathematician, astronomer and physicist Carl Friedrich Gauss discovered the basic concepts of non-Euclidean geometry but never published his work on the subject. The same year, the physicist and mathematician Joseph Fourier models the evolution of the temperature with trigonometric series.

+11809
The mathematician, astronomer and physicist Carl Friedrich Gauss developed the method of least squares independently of Legendre. The same year, the mathematician, astronomer and physicist Pierre-Simon Laplace proved the general form of the central limit theorem. The engineer, physicist and mathematician Etienne Malus publishes the law of Malus.

+11808
The physicist and chemist John Dalton proposes what is considered as the first theory of the atom. The mathematician Christian Kramp introduces in his *Éléments d'arithmétique universelle* the notation $n!$ for the factorial.

+11806
The mathematician Jean Robert Argand published the first plane representation of complex numbers and algebraic measures are used. The mathematician Johann Carl Friedrich Gauss develops the idea of adding vectors in a geometric form and introduces the notation $\overrightarrow{ab}$ for a vector.

+11805
The mathematician André-Marie Legendre developed the method of least squares.

+11803
The physicist and chemist John Dalton has the original idea to assume that each chemical element is composed of different atoms. A chemical combination was then explained by the union of these atoms in fixed proportions and relative atomic masses became calculable from experimental facts. The same year, the economist, journalist and industrialist Jean-Baptiste Say published his *Treatise on Political Economy*.

+11802

The physicist Thomas Young showed the wave nature of light by an important experience that shows the interference of waves. The same year, the chemist and physicist Joseph Louis Gay-Lussac discovered the famous law connecting gas volume and temperature of a real gas, the law that bears his name (Gay-Lussac's law).

+11801
The chemist and physicist John Dalton discovered the law of the sum of the partial pressures which still bears his name.

+11800
The chemist William Nicholson and the surgeon Anthony Carlisle used electrolysis to separate water into hydrogen and oxygen. The same year, the astronomer William Herschel discovers infrared radiation and the physicist Alessandro Volta and invented the first electric battery.

+11799
The mathematician Gaspard Monge published his book of descriptive geometry. He is considered as the inventor of this field. First satisfactory but incomplete proofs of the fundamental theorem of algebra by the mathematician Johann Carl Friedrich Gauss.

+11798
An Essay on the *Principle of Population* by the cleric and scholar Thomas Robert Malthus (one of the founding books of the study of population dynamics) proposes one of the first models of population growth, the exponential model, which will be the basis for future work.

+11798
The mathematician Carl Friedrich Gauss gives a rigorous proof of the theorem of d'Alembert (fundamental theorem of algebra). The same year, the physicist Benjamin Thompson had the idea that heat is a form of energy and the physicist and chemist Henry Cavendish measures the gravitational constant. The economist Thomas Malthus stated his law of population.

+11797
The mathematician Caspar Wessel associates vectors with complex numbers and studies complex number operations in geometrical terms.

+11793
The National Assembly of the French Republic established the metric system.

+11789
The physicists and chemists Antoine Lavoisier states the law of conservation of mass.

+11788
In his *Méchanique Analitique*, the mathematician and physicist Joseph-Louis Lagrange formulates a new way to study classical mechanics (by Isaac Newton for recall) using the principle of least action. The same year, the Academy of Science approves the creation of a universal measurement system, the future metric system. This project will also be approved by the French National Assembly in 11790, which will give the first definition of the meter.

+11787
The physicist, chemist and inventor Jacques Alexandre César Charles experimentally determined that the volume of a fixed mass of gas at constant pressure is proportional to temperature.

+11786
The astronomer William Herschel made a detailed description of our galaxy.

+11785
The physicist Charles Augustin Coulomb proves that the forces between electric charges and between magnets applied at the inverse square of the distance.

+11783
The clergyman and natural philosopher John Michell in a paper for the Philosophical Transactions of the Royal Society of London, read on 27 November 11783, first proposed the idea that there were such things as Black Holes, which he called "dark stars". A few years after Michell came up with the concept of Black Holes, the French mathematician Pierre-Simon Laplace suggested essentially the same idea in his 11796 book, *Exposition du Système du Monde*.

+11782
The mathematician, physicist and astronomer Pierre-Simon de Laplace introduces the "Laplace transform", a transformation that solves several differential equations in physics.

+11781
The chemist and physicist Joseph Priestley creates water by combustion of hydrogen and oxygen which shows that water is not an essential element as we thought since Aristotle.

+11778
The physicists and chemists Carl Scheele and Antoine Lavoisier discovered that air is composed mainly of nitrogen and oxygen. Basing his figures on the cooling rate of iron tested at his Laboratory the Petit Fontenet at Montbard, Georges-Louis Leclerc Comte de Buffon calculated that the age of the Earth was 75,000 years.

+11777
The physicist and mathematician Leonhard Euler re-introduces the letter i for the imaginary part of the complex numbers.

+11776
The moral philosopher and a pioneer of political economy Adam Smith publishes his *An Inquiry into the Nature and Causes of the Wealth of Nations*.

+11774
The mathematician, astronomer and physicist Pierre-Simon Laplace explicits Euler's integral. The same year, the theologian, dissenting clergyman, natural philosopher, educator and political theorist Joseph Priestley made his major discovery, that of oxygen.

+11772
The mathematician, engineer and astronomer Joseph-Louis Lagrange studied the three-body problem and discovered the libration points today named "Lagrange points".

+11770
In his *Mémoire sur les équations aux différences partielles*, the philosopher, mathematician, and early political scientist Marie Jean Antoine Nicolas de Caritat, Marquis of Condorcet introduces the symbol of partial derivatives ∂.

+11769
In his *Institutiones calculi integralis*, the mathematician Leonhard Euler studies for the first time the double integrals, calculates them by successive integration and changes of variable. These methods will be generalized to the triple integrals by the mathematician, engineer and astronomer Joseph-Louis Lagrange, which also gives the general formula for the change of variables (determinant of the Jacobian).

+11766
The physicist and chemist Henry Cavendish discovered and studied hydrogen.

+11764
The latent and specific heat are described for the first time by the physicist and chemist Joseph Black. It is also the first to clearly distinguish temperature and momentum. The same year, the physicist and mathematician Leonhard Euler examines the partial differential equation for the vibration of a circular drum and finds one of the Bessel function solutions.

+11763
A posthumous article of the mathematician and clergyman Thomas Bayes reveals that he discovered what is named today the "Bayes' theorem".

+11757
The physicist and mathematician Leonhard Euler founds modern hydrodynamics.

+11756
The mathematician, engineer and astronomer Joseph-Louis Lagrange develops analytical mechanics based on his invention of the calculus of variations independently of Leonhard Euler.

+11755
The physicist and mathematician Leonhard Euler introduces the uppercase Greek letter sigma ($\sum$) for the symbol of the sum.

+11753
In his 11749 study of the motions of the Earth Leonhard Euler obtained differential equations for the orbital elements and in 11753 he applied the method of variation of constants to his study of the motions of the Moon.

+11750
The mathematician Gabriel Cramer define the Cramer's rule for solving linear systems.

+11749
The astronomer and physicist Jean le Rond D'Alembert developed the first model of precession based on the theory of gravitation of Newton and gives a possible solution to the problem of three bodies.

+11748
In his *Introductio in Analysin Infinitorum* the mathematician Leonhard Euler introduces the concept of function (defined as any composition of algebraic and analytic expression), defines the concepts of even and odd functions, popularize the use of the symbols e and π, proves Euler's identity and defines the Γ function that generalized the factorial.

+11746
The encyclopedist Jean le Rond D'Alembert gives the first evidence (acceptable but will be corrected later) of the fundamental theorem of algebra. The following year (11747) he published the equation of vibrating strings, which was the first example of the wave equation. This makes D'Alembert, one of the founders of mathematical physics.

+11744
The philosopher, mathematician, physicist, astronomer and naturalist Pierre Louis Moreau de Maupertuis states the principle of least action which will be formalized mathematically 22 years later by the mathematician, engineer and astronomer Joseph-Louis Lagrange. The same year, the physicist and mathematician Leonhard Euler shows the existence of transcendental numbers and introduces variations calculus.

+11742
The astronomer Anders Celsius defines its own unit of measurement for temperature.

+11739
The physicist and mathematician Leonhard Euler solves the general homogeneous linear ordinary differential equation with constant coefficients.

+11738
The physician, physicist and mathematician Daniel Bernoulli published a book on hydrodynamics introducing the kinetic theory of gases and the famous Bernoulli theorem (pressure balance). The same year in his *Doctrine of chance*, the mathematician Abraham De Moivre introduces the Gaussian distribution as a means of approximating the binomial law for large number of experiments and demonstrates a partial version of the central limit theorem.

+11737
The physicist and mathematician Leonhard Euler solves the problem of graph theory on the bridges of Königsberg. The resolution of this problem is considered as the first theorem of graph theory. He establishes the same time the "Euler's formula" linking the number of vertices, edges and faces of a convex polyhedron, and hence of a planar graph.

+11736
The inventor Jonathan Hulls puts the first patent for a boat propelled by a steam engine.

+11734
The physicist and mathematician Leonhard Euler introduces the notation $f(x)$ for a function applied to the argument x.

+11733
The mathematician Geralamo Saccheri studies what geometry would be like if Euclid's fifth postulate were false.

+11729
The dyer and amateur of physics and astronomy Stephen Gray was the first to discover the transmission of electricity in materials that he named "conductors".

+11727
The physicist and mathematician Leonhard Euler introduces the modern notation for the

trigonometric functions and the letter e for the base of the natural logarithm (occasionally also known as the "Euler number").

+11724
The mathematician Abraham De Moivre studies mortality statistics and the foundation of the theory of annuities in Annuities on lives.

+11720
In his first Edition of this early and unusual evolutionary and geological treatise, written between 11692 and 11708, but considered so radical that even though manuscript copies began circulating in the 11720s, Benoit de Maillet estimates Earth age at 2.4 billion years old.

+11716
Christiaan Huygens was the go give a technique to estimated the absolute value of the Earth-Sun distance using a clever property of the Transits of Venus published in it's paper of 11716. In 11771 Thomas Hornsby using the observation of the transif of Venus of 11769 was able to compute the Earth-Sun distance as being approximately equal to $15,083,882.42$ [km]. Eight-tenth of a percent difference with modern measurement. Not bad!

+11715
The mathematician Brook Taylor publishes the tools that gives the possibility to make integration by parts and series expansions of functions (the famous Taylor series).

+11714
The mathematician Brook Taylor derives the fundamental frequency of a stretched vibrating string in terms of its tension and mass per unit length by solving an ordinary differential equation.

+11713
The mathematician and physicist Jacques Bernoulli publishes the rigorous principles of basic probabilities and statistics.

+11705
The astronomer Edmund (or Edmond) Halley predicted with an almost negligible calculation error that the comet which passed near the Earth in 11682 will return in 11758.

+11704
The physicist and mathematician Isaac Newton found experimentally that white light is composed of many colors. It also assumes that a light ray is composed of particles.

+11701
In his *Explication de l'Arithmétique Binaire* Gottfried Wilhelm Leibniz introduces binary arithmetic (Leibniz may have been the first computer scientist and information theorist). He anticipated Lagrangian interpolation and algorithmic information theory. His *Calculus ratiocinator* anticipated aspects of the universal Turing machine. In 11961, the mathematician and philosopher Norbert Wiener suggested that Leibniz should be considered the patron saint of cybernetics.

+11698
The mathematician and physicist Jacques Bernoulli clearly poses the problem of the brachis-

tochrone curve (which belongs to the family of cycloid curves) and proposes a solution. The same year, the mathematician Guillaume de L'Hopital states his rule for the examination of indeterminate forms. Gottfried Leibniz proposes the use of the point · to denote multiplication, instead of the cross ×, which is too easily confused with the variable x in the equations.

+11696
The mathematician and physicist Jacques Bernoulli clearly poses the problem of the brachistochrone curve (which belongs to the family of cycloid curves) and proposes a solution. The same year, the mathematician Guillaume de L'Hopital states his rule for the examination of indeterminate forms.

+11693
The astronomer and engineer Edmund Halley discovered the relation between the focal length of a lens with the distance of the image to its axis and the real object to its axis. The same year, he prepares the first mortality tables statistically relating death rate to age.

+11691
The philosopher and mathematician Gottfried Leibniz discovers the technique of separation of variables for ordinary differential equations.

+11690
The wave theory of light is put forward by the physicist and astronomer Christiaan Huygens. The same year the physicist and mathematician Johann Bernoulli developed the exponential calculus and find the equation of the catenary. The same year, the mathematician and physicist Jacques Bernoulli (brother of Jean Bernoulli) develops integral calculus.

+11687
The physicist and mathematician Isaac Newton published *Naturalis Principia Mathematica* in which he explains the force of gravity and planetary orbits. He also describes the three laws of dynamics and derivates Kepler laws for his gravitational law. This is the first scientific revolution (before Special/General Relativity and quantum physics).

+11685
The philosopher and mathematician Gottfried Leibniz solves linear systems using without theoretical justification matrices and determinants.

+11682
The physicist and mathematician Isaac Newton establishes the law of gravitation, which now bears his name.

+11679
The philosopher and mathematician Gottfried Leibniz introduces binary arithmetic and develops a calculating machine that performs 4 operations. The same year, the physicist, mathematician and inventor Denis Papin shows experimentally the influence of atmospheric pressure on the boiling point of water.

+11678
The mathematician, astronomer and physicist Christiaan Huygens states his principle of wavefront sources.

+11676
The physicist Robert Hooke states that stretching a spring is proportional to the stress.

+11675
The astronomer Olaus Roemer makes accurate measurements of the speed of light. The same year, the apothecary chemist Nicolas Lemery writes *Cours de chymie* which is considered as the first great chemistry treatise where the mixtures are defined, the first theory of bases and acids, and so on are introduced and the physicist and astronomer Isaac Newton invents an algorithm to calculate the function roots.

+11673
The philosopher and mathematician Gottfried Leibniz invents his differential calculus, introduces the symbol $\int$ and use the term "convergence test" for alternated series and use the definition of the convergence for the first time. Leibniz also use the notation $\mathrm{d}y/\mathrm{d}x$ and $\mathrm{d}x$, $\mathrm{d}x$.

+11671
First attempt to calculate life annuities (comparable to life insurance) by the politician Johan de Witt in collaboration with the mathematician Christian Huygens and first calculations of life expectancy.

+11670
The mathematician John Wallis introduces the symbols $\leq$ and $\geq$.

+11669
The mathematician, astronomer and physicist Christian Huygens published results on the observation of the conservation of kinetic energy becoming verbatim the discoverer of the concept of kinetic energy. The same year, in his manuscript *De analysi per aequationes numero terminorum Infinitas*, the physicist and astronomer Isaac Newton gives the first description of the Newton's method which makes it possible to find approximations of function roots by iterated process. The description of Newton only applies to polynomials and does not use the notion of derivative (the manuscript will be published in 11711).

+11668
The physicist and astronomer Isaac Newton made the first reflecting telescope and the same year the mathematician John Wallis suggests the law of conservation of momentum.

+11667
In his *Vera Circuli and Hyperbolae Quadratura* the mathematician and astronomer James Gregory gives the first proof of the fundamental theorem of calculus and independently discovers Taylor series. Draft of the concept of transcendental number elaborated in relation to the problem of the quadrature of the circle.

+11665
The physicist Isaac Newton formulated the three laws of mechanics. He lays the foundations of differential calculus, these techniques allows him starting from the expression of a force inverse of square of the distance to find the general form of Kepler's laws.

+11664
The physicist Isaac Newton begins to work on differential and integral calculus.

+11661
The founder of statistical demography John Graunt published the first mortality table, the same year the physicist and chemist Robert Boyle determines the laws of compressibility of gas bearing his name and sometimes attached to that of the physicist Edme Mariotte who rediscovered a few years after the same laws.

+11659
The mathematician, astronomer and physicist Christian Huygens discovered the rigorous isochronism formula (when the end of the pendulum travels an arc of cycloid, the period of oscillation is constant regardless of the amplitude).

+11658
The mathematician, astronomer and physicist Christian Huygens experimentally discovers that balls placed anywhere inside an inverted cycloid reach the lowest point of the cycloid in the same time and thereby experimentally shows that the cycloid is the isochrone.

+11657
The lawyer and mathematician Pierre de Fermat states his "Fermat's principle" in optics as how the light propagates from one point to another on trajectories such that the duration of the propagation is locally minimal.

+11655
The mathematician, astronomer and physicist Christian Huygens was the first to use the concept of expected mean in probabilities. The mathematician John Wallis introduces the symbol ∞ in his *Mathesis Universalis*.

+11654
The mathematician, physicist, inventor, philosopher, moralist and theologian Blaise Pascal and the lawyer and mathematician Pierre de Fermat create the theory of probability. The world's oldest national scientific institution, the Royal Society, is founded in London. It establishes experimental evidence as the arbiter of truth.

+11650
James Ussher (archbishop) began counting all the "begats" in the Old Testament (...) He also studied ancient Egyptian and Hebrew texts, analysed how the ancient calendars were calculated and came up with a date for the Creation that Earth was about 5,650 years old.

+11644
The physicist and mathematician Evangelista Torricelli has the idea of substituting water by mercury in the so named Torricelli's experiment to highlight the "grosso-vido"; later will the works of the mathematician, physicist, inventor, philosopher, moralist and theologian Pascal Blaise follow (experience Puy de Dôme experiment).

+11638
The mathematician, geometer, astronomer and physicist Galileo Galilei publishes the mathematical relationship that defines the period of the simple pendulum.

+11637
The philosopher and mathematician René Descartes renames the unknowns x, y, z and the parameters a, b, c and extends the use of algebra to the lengths and plane, creating analytical

geometry with Pierre de Fermat. The same year, always René Descartes, quantitatively derives the angles at which primary and secondary rainbows are seen with respect to the angle of the Sun's elevation.

+11631
The mathematician Thomas Harriot introduces, in a posthumous publication, the symbols $>$ and $<$. The same year the theologian and mathematician William Oughtred provides for the first time the multiplication symbol $\times$ and the symbol $\pm$.

+11629
The lawyer and mathematician Pierre de Fermat develops a rudimentary differential calculus. The same year, in his *Invention nouvelle en algèbre* Albert Girard states, without proof, for the first time the fundamental theorem of algebra (a polynomial of degree n has n complex distinct or non-distinct roots) using complex numbers.

+11626
Tables of sine, tangent and secant of the engineer Albert Girard with the use of abbreviations sin, cos and tan.

+11624
Invention of the first thermometer (whose graduations are obviously not standardized...) by the physician Santorio Santorio.

+11621
The astronomer and physicist Willebrord Snell discovered that the angle of refraction of light is determined by the sine of the angle of the incident light with the normal of the dioptre.

+11620
The engineer Francis Thomas Bacon defends the experimental method (it seems he was the first one to document the Scientific Method) and leads numerous observations on heat. He suggested that heat is related to movement.

+11619
Johannes Kepler finished to publish the three laws of planetary motion.

+11614
The mathematician John Napier invented logarithms, which bring the operations of multiplication and division to simple additions or subtractions.

+11611
Johannes Kepler discovers total internal reflection, a small angle refraction law and thin lens optics.

+11610
In his *Sidereus Nuncius*, Galileo Galilei reports the first observations at the telescope: the discovery of the satellites of Jupiter, the confirmation that the milky way is constituted of stars, the discovery of the rings of Saturn. These observations will have an important effect because they contradict some of the ideas of the Universe models of the time and the Bible scriptures.

+11609

In his *Astronomia Nova*, the astronomer and mathematician Johannes Kepler explains Kepler's first two laws for the motion of the planets.

+11608
The optician Hans Lippershey invented the telescope to will be used and improved (with a random quality) the following year by the mathematician, geometer, astronomer and physicist Galileo Galilei to confirm the theories of Copernicus.

+11604
In a letter to Paolo Sarpi, Galileo states the law of the fall of bodies: the distance travelled is proportional to the square of the time of fall.

+11603
The mathematician and astronomer Thomas Harriot determines how to calculate qualitatively the surface of a spherical triangle.

+11596
The quantitative history of variable stars begins with David Fabricius 11596 observations of the appearance and disappearance of omicron Ceti (Mira). The eclipsing variable star Algol was first noted by Gernian Montanari in 11667, but its period of 2.867 days was not measured until the 11783 work of Nathaniel Pigott, John Goodricke and Johann Georg Palitzsh. However the idea of variability of Algol of Miras was known in ancient times by Babylonians between 8105 and 9461 (see Schaumberger, J. 11935 *Sternkunde und Sterndienst in Babel*, vol. 3, Verlag der Aschendorffschen Verlagsbuchhandlung) and Chinese (9750 to 9975).

+11591
The mathematician François Vieta opens a new period int algebra by making calculations with letters, using vowels for unknowns and consonants for parameters. Moreover, he gives the development of the Newton binomial theorem.

+11590
The astronomer Galileo Galilei demonstrated experimentally that all falling bodies have the same acceleration. The same year, the opticians Hans and Zacheraius Janssen created the first microscope by combining several lenses that define the beginnings of scientific medicine and biology.

+11586
The engineer and physicist Simon Stevin proved the method of the parallelogram of forces and discovered that the pressure of a liquid on the bottom of a container is independent of its shape, and also of the bottom surface and depends only on the height water in the container. He also gave the pressure measurement on any portion of the side of a container.

+11584
Giordano Bruno proposed that the stars were distant suns surrounded by their own planets, and he raised the possibility that these planets might foster life of their own, a cosmological position known as cosmic pluralism. He also insisted that the universe is infinite and could have no "center". Bruno also largely anticipated the arguments of Galilei on the relativity principle

+11576
The astronomer Tycho Brahe observed a new star in the constellation of Cassiopeia and built an

observatory on the island of Hveen.

+11572
The mathematician Rafaelle Bombelli gives a formulation of complex numbers and the rules of actual calculations. He introduces the terms più di meno (pdm) and meno di meno (mdm) to represent $+\mathrm{i}$ and $-\mathrm{i}$.

+11548
The mathematician and physicist Simon Stevin wrote the tenth powers identified with an exponent. He also gives the first writing of vectors.

+11545
The mathematician Ludovico Ferrari gives the solution of equations of degree 4 (know under "Cardan formula").

+11543
The work of the astronomer Nicolas Copernicus summarizing 26 years of research and observations is published and clearly highlights that the heliocentric system of Ptolemy is not valid (before Nicolas Copernicus, Nicole Oresme (around 11322 – 11382) had already presented the heliocentric system as credible, however, Nicolas Copernicus also brings the mathematical, that is to say geometric, demonstration of its validity, however models in which the Earth was not at the center of the World had been proposed since Antiquity such as that of Aristarchus of Samos around 9690 – 9770).

+11536
The mathematician Niccolò Fontana launched the new science of ballistics.

+11530
The mathematician and physicist Robert Recorde introduces the "$=$" sign and the mathematician Michael Stifel developed an early form of algebraic notation.

+11525
The mathematician Christoff Rudolff introduces the notation for square roots $\sqrt{}$.

+11515
Publication of Scipione del Ferro's works where he find a formula giving the general solution of the polynomial equations of degree 3. These solutions involve the implicit manipulation of imaginary numbers

+11510
The painter, engraver and mathematician Albrecht Dürer develops the basics of descriptive geometry and perspective.

+11500
The Italian mathematician Scipione del Ferro succeeds for the first time to solve a large algebraic type of cubic equations.

+11490
The painter, sculptor, architect, musician, mathematician, engineer, inventor, anatomist, geologist, cartographer, botanist, and writer... Leonardo da Vinci describes capillary action.

+11489
In his *Behende und hupsche Rechnung auf allen kauffmanschafft*, the mathematician Johannes Widmannwe the symbols "$+$" and "$-$" are introduced for the first time (before plus was denoted "P" and minus "M").

+11464
In *Triparty in the science of numbers* by the mathematician Nicolas Chuquet we can find the first use of negative powers and zero power and the statement of the property of exponents that we still use $x^{n+m} = x^n x^m$.

+11420
The mathematician and astronomer Jamshid al-Kashi computed and observed the solar eclipses of 11406, 11407 and 11408. He is also the first to use decimal notation in arithmetic and in arabic numerals.

+11400
The Mathematician and astronomer Jamshid al-Kashi developed an early form of Newton's Regula falsi method.

+11200-11400
Madhava and the Kerala School (India) discover several infinite series for numbers like π and specific values of trigonometric functions - these works ahead of those of the Europeans on the differential and integral calculus and the series of powers.

+11350
Tractatus of configurationibus qualitatum and motuum of Nicole Oresme is a draft of geometry using coordinates, and use axes for different sizes, which is an important step in the transition from qualitative science based mainly on Aristotle to quantitative science. Proof of the mean velocity theorem, which anticipates the results of Gallileo on the uniform rectilinear motion and the bodies in free fall by linking area under the curve of the velocity to the position in a graph.

+11303
Siyuan Yujian (translation: *Precious mirror of elements*) of Zhu Sjijie describes the elimination method for solving systems of equations containing up to four unknowns and up to degree 14 for some form of equations. We also find there the definition of the Pascal's triangle and the formulas of summations for some series.

+11300
Raymon Lulle developed a geometric (useless) machine to automate theist logic. This idea will influence Leibniz in his research of a universal language for reasoning, research that will lead him to take an interest in Chinese writing and binary arithmetic. Lulle's ideas anticipate modern ideas of formal deduction systems.

+11269
The scholar Pierre de Maricourt coined the expressions of the magnetic "north" and "south poles" and he was the first who wrote that opposite poles attract each other.

+11268
The philosopher, scientist and alchemist Roger Bacon publishes proposals to reform school, arguing that to study nature, the use of observations of the measures is the only basis of rigor-

ous testing and verification while affirming at the same time the need of mathematics for this purpose.

+11200
The mathematician Jordan Nemore introduces the notation for unknowns with symbols.

+11150
Creation of modern notation for fractions (horizontal bar) by Al-Hassãr. At the same period, we have the Latin translation of the 820 treaty by Muhammad Ibn Musa al-Khwarizmi on the Indian calculation which allows the decimal system and the use of zero to spread in Europe and also Gérard de Cremona publishes a translation in Latin of the Arabic version of the *Almagest* of Ptolemée, the name "sinus" comes from this translation...

+11121
The astronomer, physicist, biologist, chemist, mathematician and philosopher Abu al-Fath Khazini published a book in which he proposed that gravity and gravitational potential energy vary with distance from the center of the Earth. He also makes a distinction between force, mass and weight. He also invented several scientific instruments, including a steelyard and hydrostatic balance. He also introduces experimental scientific methods to static and dynamic, unifies them in the science of mechanics and combines hydrostatics with the dynamic to create hydrodynamics.

+11114
The mathematician Bhaskara provides a comprehensive summary of Hindu mathematics, as developed from the 5th to the 7th century AD. He also recognizes the negative square root, solves quadratic equations with several unknowns, equations of higher order such as Fermat and the general quadratic equations. He was also a pioneer in the principle of differential calculus nearly 500 years before Newton and Leibniz.

+11100
The philosopher and physicist Allah Abu'l-Barakat Hibat al-Baghdaadi is the first to deny Aristotle's idea that a constant force produces uniform motion what prepares the Newton's second law of motion. Like Newton, he described acceleration as the variation of speed.

+11037
The mathematician, physicist and philosopher Ibn al-Haytham is aware of the magnitude of the acceleration due to gravity. He discovers the law of inertia, known today as the first law of motion Newton.

+11030
The philosopher, writer, physician and scientist Abu Ali al-Husayn ibn Abd Allah Ibn Sina (known in Occident as Avicenna) note that if the perception of light is due to the emission of some sort of particles by a light source, the speed of light has to be finished. He also provided a sophisticated explanation for the phenomenon of rainbow. The mathematician, astronomer, physicist, scholar, encyclopedist, philosopher, astrologer, traveller, historian, pharmacologist Abu Ali al-Husayn ibn Abd Allah Ibn Sina, and later the astronomer Abu al'Fath Khazini, were the first to apply the scientific method in experimental mechanics, especially in the fields of statics and dynamics, to determine the specific weight, such as those based on the theory of balances and weighting.

+11021
The philosopher, mathematician and physicist Ibn al-Haytham is considered as the father of optics and one of the pioneer of the scientific method to describe quite correctly the light and vision, and to introduces the experimental scientific method, laying the foundations of experimental physics. He also discusses experimental psychology and describes various optical instruments such as the darkroom. He was able to estimate atmosphere width with an accuracy of 1 [km], he defined the inertia principia (first Newton's law), the linear momentum and he calculated $\sum_{k=1}^{n} k^4 = \frac{n(2n+1)(n+1)(3n^2+2n-1)}{30}$.

+11019
The mathematician, astronomer and physicist Muhammad Ibn Ahmad Abul-Rayhan Al-Biruni observed and described the solar eclipse of April 8, 11019, and the lunar eclipse of September 17, 11019, in detail; he gave the exact location of the stars during the lunar eclipse. He invented the astrolabe and the planisphere.

+11010
The mathematician Al-Sijistani Zuraqi invented a astrolabe designed for a single heliocentric planetary model in which the Earth is moving, rather than the sky.

+11000
The mathematician, physicist and astronomer Abu Sahl al-Qouhi discovers that the weight of bodies varies with their distance from the center of the Earth, and solves equations higher than the second degree. During the same decade, the mathematician and engineer Ma'ruf al-Karkhi wrote a book containing the first known proof by mathematical induction. He uses it to prove the binomial theorem, the Pascal's triangle, and the sum of the cubes integrals.

+10996
The mechanical oriented astrolabe, with 8 gears is invented by the mathematician, astronomer and physicist Muhammad Ibn Ahmad Abul-Rayhan Al-Birun who is also the author of works on the summation of series and combinatorics.

+10980
Abu al-Wafa' Buzjani do the first calculation of values of trigonometric functions and publish the sinus law adapted for triangles on sphere. He also proved by induction $\sum_{k=0}^{n} k^3 = \frac{n^2(n+1)^2}{4}$.

+10964
The mathematician, physicist and philosopher Abd al-Rahman al-Sufi explains the magnifying power of lenses and he was one of the first to use a scientific method of analysis that will greatly influence future scientists.

+10953
The engineer and mathematician Ma'ruf al-Karkhi defines different monomials and gives rules for products of any two of them. He also discovered the binomial theorem for integer exponents.

+10952
The mathematician Abu'l-Hasan al-Uqlidisi modifies the calculation methods for the numerical Indian system to make it possible for feathers and paper usage. Until then, do calculations with Indian numerals necessitated the use of a board.

+10900
The first reference to a viewing tube can be found in the work of the astronomer and mathematician Al-Battani, and the first accurate description of the observation tube was given by the mathematician, astronomer, physicist, scholar, encyclopedist, philosopher, astrologer, traveller, historian, pharmacologist Muhammad Ibn Ahmad Abul-Rayhan Al-Biruni, in a section of his work dedicated to verify the presence of the new crescent Moon at the horizon. Although these preliminary observations tubes do not have lenses, they allow an observer to focus on a part of the sky by eliminating light interference. These observation tubes were later adopted in Europe, where they influenced the development of the telescope.

+10880
The astronomer and mathematician Al-Battani discovered the motion of the apogee of the Sun, calculate the values of the precession of the equinoxes and the inclination of the Earth's axis. He is at the origin of the definition of the tangent and cotangent trigonometric functions.

+10820
The word "algebra" appears. The mathematician, geographer, astrologer and astronomer Muhammad ibn Musa Al'Khwarizmi is often regarded as the father of medieval algebra because he releases it from geometry. He is also the origin of the quadrant, the mural instrument, the sinus quadrant that was used to solve trigonometric problems and make astronomical observations.

+10800
Astronomers invent the universal sundial and universal time dial in Baghdad. Earliest writing we get about statistical inference by Abu Yusuf Ya'qub Ibn Al-Kindi on how to use statistics and frequency analysis to decipher encrypted message. His text seems arguably gave rise to the birth of both statistics and cryptanalysis.

+10780
The alchemist Jabir Ibn Hayyan introduces the experimental scientific method for chemistry and also laboratory equipment such as still and processes such as pure distillation, liquefaction, crystallisation and filtration. He also invented more than 20 types of laboratory equipment, which resulted in the discovery of several chemicals. He also developed recipes for coloured glass.

+10773
Arabic numerals (adapted from India) made their first apparition in Europe.

+10628
The mathematician Brahmagupta gives rules for solving linear and quadratic equations. He discovers that the quadratic equations have two roots: the negative one and the irrational and give the modern form of the solution we know today. He also give the rules to calculates with negative signs (arithmetic of negative numbers).

+10550
Hindu mathematicians give zero a numeral representation in a positional notation system. *Brahmagupta's Brahmasphutasiddhanta* is the first book that provides rules for arithmetic manipulations that apply to zero and to negative numbers. The *Brahmasphutasiddhanta* is the earliest known text to treat zero as a number in its own right, rather than as simply a place-holder digit

in representing another number as was done by the Babylonians.

+10499
The mathematician Âryabhat gets the full number of solutions of a system of linear equations by methods equivalent to modern methods, and describes the general solution of such equations. He also provides solutions of differential equations. He also asserts that the Moon and celestial objects other than the stars reflect sunlight (almost 1000 years later after the poems of Parmenide claining the same), he correctly explains the causes of lunar and solar eclipses, gives the length of the sidereal year to a few minutes, approximate π by $62832/20000$, calculates the Earth's diameter with more precision than Eratosthenes, described the calculation with the Indian numbering system, gives the oldest sinus table for 24 angles.

+10275
The mathematician Diophantus of Alexandria considered as the father of algebraic equations studied equations with rational variables (thus including quadratic equations) and Diophantine equations.

+10195
Suàn shù shu (translation: *book on numbers and calculation*) is one of the oldest known Chinese mathematical texts that contains among other things, calculations of sums of Geometric progression for interest.

+10130
Mathematical Composition (also know under the name of *Almagest's*) of Ptolemy in Alexandria presents a geometric model of the solar system that attempts to describe the motion of the planets. The model is inspired by a geometric idea of Apollonius of Tyana and uses circles whose center move in circular orbits. This model puts the Earth at the center of the solar system but gives a fairly good description of the observed movements of the different stars. It will be the dominant model until Copernicus. Some ideas prefigure the Fourier series that will be introduced in the 19th century.

+10125
The *Yale Music Papyrus* and the *Michigan Instrumental Papyrus* seems to contain the oldest known examples of musical notation.

+10121
Year corresponding to the oldest document mentioning the magnetic stone.

+10120
Star catalogue of Zhang Heng which contains $2,500$ stars. Zhang Heng correctly describes the cause of the eclipses and demonstrates that the Moon is spherical.

+10100
The engineer, mechanician and mathematician Hero of Alexandria rediscovered (after the Chinese) the concept of force. He also invented a system of gears to lift weights using steam power. He gives the first description of the sextant (but did not, however, invented it). His contemporary astronomer Claudius Ptolemy invented the sextant and described the astrolabe (perhaps invented by the astronomer, geographer and mathematician Hipparchus) and studied the refraction and reflection. During the same century the mathematician and philosopher Nicomachus of Gerase defines the even and odd numbers, prime and composite numbers, and perfect numbers. Also

during the same century the final version of the *Nine Chapters on Mathematical Art* (almost 1180 pages), written over ten years by several anonymous Chinese authors contains the first use of negative numbers, chapter 9 uses the Pythagorean theorem, chapter 8 uses matrices and the elimination of Gauss to solve systems of equations (at least 1700 years before Gauss!!!)

+10080
The scholar Wang Ch'ung made the first magnetic compass on a plate of brass.

+9923
Year corresponding to the dating of the Antikythera mechanism, considered as the first calculator and the first antique analogue gear (thirty!) machine to calculate complexes astronomical positions. The care and skill with which this machine was made, as well as the necessary mechanical and astronomy capacities question the historical knowledge of Greek science before its discovery. Indeed, any object of the same age and same complexity was known in the world and it takes nearly a millennium to see similar mechanisms appear! The physicist, mathematician and engineer Archimedes of Syracuse is the hypothetical creator.

+9900
The indian text *Anuyoga Dwara Sutra* contains several identities involving square roots and squares that seem to imply some knowledge of the laws of exponents or logarithms. An identity taken from this text in modern notation: $\sqrt{a}\sqrt{\sqrt{a}}=(\sqrt{\sqrt{a}})^3$.

+9866
The astronomer, geographer, and mathematician Hipparchus of Nicaea discovers the precession of the equinoxes.

+9850
The astronomer, geographer and mathematician Hipparchus is often referred as the founder of trigonometry and corresponding numerical tables. He calculates the first period of revolution of the Sun around the Earth (but the numerical results are in fact those of the rotation of the Earth around the Sun) and develops the theory of eccentrics and epicycles.

+9800
During the century, the Chinese had invented the tide gate, the rudder, the principle of the steam engine several hundred years before the Occident! During this century, the scientist and engineer Philo of Byzantium wrote treatises on levers, pneumatics, automation, traction and water clocks.

+9775
The astronomer and mathematician Apollonius of Perga published the first study on conics giving to the ellipse, the parabola and the hyperbola the names we know today. He is also credited for the hypothesis of eccentric orbits to explain the apparent motion of the planets and the speed variation of the Moon.

+9750
The mathematician, physicist and engineer Archimedes of Syracuse study simple machines such as the lever, the famous screw for pumping water ("Archimedes screw") and discovered the Archimedes's principle explaining buoyancy. In the same decade, the astronomer, geographer, philosopher and mathematician Eratosthenes of Cyrene calculated the diameter of the Earth using a gnomon and its shadow and demonstrated the inclination of the ecliptic, the distance

Earth-Moon and Earth-Sun and also created a method to determine prime numbers (Sieve of Eratosthenes).

+9740
The mathematician, physicist and engineer Archimedes of Syracuse computes to two decimal places using inscribed and circumscribed polygons and computes the area under a parabolic segment.

+9719
The astronomer and mathematician Aristarchus of Samos assumed that the Sun is the center of the solar system (heliocentrism model) and uses trigonometry to estimate the radius of the Moon and its distance from the Earth using the Earth's shadow during a lunar eclipse. He also estimated the Earth-Sun distance in number of times the Moon-Earth distance (...).

+9700
The mathematician and geometer Euclid published his *Elements*, where he reorganized the entire knowledge of the geometry including logical proofs, the construction of the 5 Platonic solids. In his *Optica* he noted that the light goes in a straight line and describes the law of reflection. We have also that the conical, elliptical, parabolic and hyperbolic concepts appears in the works of two mathematicians of the ancient Greece, namely Menaech-mus and Appolonius de Perge that also introduces the concept of tangent. The same period Bhagabati Sutra calculates the permutations and combinations of order 1, 2 and 3.

In Hindu cosmology, the Manusmriti (1.67–80) and Puranas describe time as cyclical, with a new universe (planets and life) created by Brahma every 8.64 billion years. The universe is created, maintained, and destroyed within a kalpa (day of Brahma) period lasting for 4.32 billion years, and is followed by a pralaya (night) period of partial dissolution equal in duration. In some Puranas (e.g. Bhagavata Purana), a larger cycle of time is described where matter (mahat-tattva or universal womb) is created from primal matter (prakriti) and root matter (pradhana) every 622.08 trillion years, from which Brahma is born. The elements of the universe are created, used by Brahma, and fully dissolved within a maha-kalpa (life of Brahma; 100 of his 360-day years) period lasting for 311.04 trillion years containing 36,000 kalpas (days) and pralayas (nights), and is followed by a maha-pralaya period of full dissolution equal in duration. The texts also speak of innumerable worlds or universes.

+9690
The scholarly Autolycus of Pitane defines uniform motion as an object that travels an equal distance in a equal amount of time.

+9630
The philosopher Aristotle develops the logic with a theory of naive proposals, quantities and inferential reasoning. He also wrote a treatise on meteorology named *Meteorologica*. It is crystal clear from this treatise that he already understood the cycle of water and knew that clouds were made of evaporated water and are therefore very heavy structures. He also knew (in a naive way) and tested experimentally how salt water and normal water were separated and mixed in the seas. Aristotle pioneered scientific method alongside his empirical biology and his work on logic, rejecting a purely deductive framework in favour of generalisations made from observations of nature. Aristotle mentioned also that salt water (of the sea) was heavier and more dense than fresh water, and salt water would seek a lower level.

+9622
The philosopher and astronomer Heraclides Ponticus assumes the rotation of the Earth itself to explain the apparent motion of stars in the night (but still in a geocentric context) and suggests that each planet is a body like the Earth.

+9600
The Stoic School develops the composed proposals and the logical connectors: "implies", "and", "or" and the inferences "Modus ponens" and "Modus tollens".

+9580
Philolaos publish his System of the World where the Earth turns around a central fire.

+9530
The philosopher Democritus of Abdera advance the idea that matter is composed of tiny and identical particles that he named "atoms". In reality it is rather an extension of the ideas of his teacher, the philosopher Leucippus of Miletus developed ten years before. Hippasus, a disciple of Pythagoras, would have given what is probably the first rigorous proof of the irrationality of $\sqrt{2}$. The proof uses a Reductio ad absurdum reasoning to show that the sides of a square are incommensurable with its diagonal. Least known written use of statistics by the historian Thucydides in his *History of the Peloponnesian War* (use of the Mode).

The oldest known record of the Camera Obscura is a description by Han Chinese philosopher Mozi (ca. 9530 to ca. 9609). Mozi correctly asserted that the camera obscura image is inverted because light travels in straight lines from its source. In the 11th century Arab physicist Ibn al-Haytham (Alhazen) wrote very influential books about optics, including experiments with light through a small opening in a darkened room.

+9533
Anaxagoras produced a correct explanation for eclipses and then described the Sun as a fiery mass larger than the Peloponnese, as well as attempting to explain rainbows and meteors. He was the first to explain that the Moon shines due to reflected light from the Sun.

+9500
The philosophers Leucippus and Democritus are the founders of atomism. Yajnavalkya, in his *Shatapatha Brahmana*, describes the motions of the Sun and the Moon, and advances a 95-year cycle to synchronize the motions of the Sun and the Moon.

Period of earliest documented mention of the concept of spherical Earth dates from around the 95th century, when it appears in the writings of Greek philosophers. In the 93th, Hellenistic astronomy established the roughly spherical shape of Earth as a physical fact and calculated the Earth's circumference. This knowledge was gradually adopted throughout the Old World during Late Antiquity and the Middle Ages.

+9460
The philosopher, mathematician Pythagoras studies propositional geometry and vibrating lyre strings.

+9415
Thales of Miletus predicts a solar eclipse.

+9400
The philosopher Empedocles of Acragas calls for decomposition of the world into four fundamentals elements: water, earth, air and fire. The same century, the mathematician Thales of Miletus highlights electrostatic by rubbing a piece of amber, predicted an eclipse and develops the geometry of the triangle.

Greek philosophers, as early as Anaximander, introduce the idea of multiple or even infinite universes. Democritus further detailed that these worlds varied in distance, size; the presence, number and size of their suns and moons; and that they are subject to destructive collisions. Also during this time period, the Greeks established that the Earth is spherical rather than flat.

+9250
Sulbar Sutras of Manava finds irrationality of $\sqrt{2}$ and $\sqrt{61}$ and agrees to use irrational numbers in his calculations. The first known university (using strictly the definition of that word which is derived from the Latin *universitas magistrorum et scholarium*, which roughly means "community of teachers and scholars") was created at Miletus (where Thales studied). Notice that the word "universiy" seems to exist since only the 113 century.

+9200
Assyrians use water-clocks and Chinese plot planetary movements for their calendar.

+9105
In approximately 8705 a new hieroglyphic word appeared. Bia-n-pet literally translates as “iron from the sky”. The new word was applied to all metallic iron from this time onwards. An obvious explanation for the sudden emergence of the new word would be a major event, such as a large impact or shower of meteorites, witnessed by the ancient Egyptian population. This would have left little uncertainty as to where exactly the mysterious iron came from, and would have created a sufficiently strong association between iron and the sky for the new word to become synonymous with all forms of iron. In 12008 a large impact crater formed by an iron meteorite was found in southern Egypt. Although its exact age is unknown, local archaeology suggests that it formed within the last 5000 years, making it a possible candidate event.

+8600
The Neolithic peoples of Scotland nowadays build stone models of Plato’s five solids (regular polyhedra). Hindous claim using concordism that the *Rigveda* hymn 1:50 (50th hymn in book 1 of Rigveda) leads to the calculation of the speed of light.

+8500
Indians develops theory of the 4 elements (fire, air, water, earth). Babylonians develop earliest known algorithms for factorization and finding square roots.

+8300
The mathematician Apastamba Dharmasutra solved general linear equations and used Diophantine systems of equations with up to five unknowns. The same century, egyptian mathematicians employ primitive fractions and develop earliest known algorithms for multiplying two numbers.

+8200
The origins of algebra can be traced to the ancient Babylonians, who developed a positional number system that greatly aided them in solving their rhetorical algebraic equations. The Babylonians were not interested in exact solutions, but rather approximations, and so they would

commonly use linear interpolation to approximate intermediate values. One of the most famous tablets is the Plimpton 322 tablet, created around 8100-8400, which gives a table of Pythagorean triples and represents some of the most advanced mathematics prior to Greek mathematics. Babylonian algebra was much more advanced than the Egyptian algebra of the time; whereas the Egyptians were mainly concerned with linear equations the Babylonians were more concerned with quadratic and cubic equations. The Babylonians had developed flexible algebraic operations with which they were able to add equals to equals and multiply both sides of an equation by like quantities so as to eliminate fractions and factors. They were familiar with many simple forms of factoring, three-term quadratic equations with positive roots, and many cubic equations, although it is not known if they were able to reduce the general cubic equation.

+8200
It was known during Vedic and later times (*Rigveda*, I, 19.7, I 23.17, I, 32.9,VIII, 6.19; VIII, 6.20; and VIII, 12.3) (Sarasvati, 12009) that water is not lost in the various processes of the hydrological cycle, namely, evaporation, condensation, rainfall, streamflow, etc., but gets converted from one form to another (transfer of water from the Earth to the atmosphere by the Sun and wind).

+8000
Babylonian priests do the first records of celestial observations. The Babylonians use a base-60 positional numeral system, and compute the first known approximate value of π at 3.125.

+7700
Chinese astronomers make the first observations of the sky.

+7500
The Mesopotamians imagined a position numbering system composed of symbols whose value is based on their rank within a number. Average estimate age of Stonehenge (England) as multifunctional site but which might have allowed prediction of eclipse, solstice, equinox and other celestial events.

+7400
Oldest known mathematical table where a multiplication table is engraved to calculate areas.

+7000
Chinese and Babylonians invented the abacus as first adding machine. Geometric concepts are developed for land surveying (hypotenuse calculus). It is also the period corresponding to the oldest know tool used by Incas to record numbers thanks to knots on a string and also the wall representation of wheels.

+6900
Egypt, earliest known decimal system allows indefinite counting by way of introducing new symbols. Mayan astronomers discover an 18.7-year cycle in the rising and setting of the Moon. From this they created the first almanacs – tables of the movements of the Sun, Moon and planets for the use in astrology. In 94th century in Greece, this knowledge was used to predict eclipses.

+6500
Dating of the oldest weather report found on a stone in Egypt. The unusual weather patterns described on the slab were the result of a massive volcano explosion at Thera, the present day

island of Santorini in the Mediterranean Sea.

+6300
A Babylonian tablet seems to contain first remarkable trigonometric angles and the evidence that Pythagoras' theorem was already known by Babylonians.

+6100
The Goseck circle (German: Sonnenobservatorium Goseck) may be one of the oldest Solar observatories in the world.

+5000
The decimal system is used in Ancient Egypt (it seems that the consensus is between 4000 and 7000).

+4800
Radiocarbon dating of the oldest founded wheels (Ljubljana Marshes wooden Wheel).

+2000
Warren Field is the location of a Mesolithic calendar. It includes 12 pits believed to correlate with phases of the Moon and used as a lunar calendar. It is considered to be the oldest lunar calendar yet found. Marks on bones or woods are slowly replaced by tokens of various shapes to count.

-1000
Supposed age of the oldest astronomical observatory in the world named Wurdi Youang (aboriginal stone arrangement located off the Little River – Ripley Road at Mount Rothwell, near Little River, Victoria in Australia).

-10000
The Ishango bone (Nile Valley) is a bone tool, dated to the Upper Paleolithic era (see [302]). It is a dark brown length of bone, the fibula of a baboon, with a sharp piece of quartz affixed to one end, perhaps for engraving. It was first thought to be a tally stick, as it has a series of what has been interpreted as tally marks carved in three columns running the length of the tool. It has also been suggested that the scratches might have been to create a better grip on the handle or for some other non-mathematical reason.

-25000 to -10000
Africa and France, earliest known prehistoric attempts to quantify time.

-190000
Claims for the earliest definitive evidence of control of fire by a member of Homo range from 0.2 to 1.7 million years ago. Evidence for the controlled use of fire by Homo erectus, beginning some 400,000 years ago, has wide scholarly support.

20.1. Situations

An engineer, a physicist, and a mathematician are shown a pasture with a herd of sheep, and told to put them inside the smallest possible amount of fence.

- The engineer is first. He herds the sheep into a circle and then puts the fence around them, declaring:"A circle will use the least fence for a given area, so this is the best solution."
- The physicist is next. She creates a circular fence of infinite radius around the sheep, and then draws the fence tight around the herd, declaring, "This will give the smallest circular fence around the herd."
- The mathematician is last: After giving the problem a little thought, he puts a small fence around himself and then declares, "I define myself to be on the outside!"

Two men are sitting in the basket of a balloon. For hours, they have been drifting through a thick layer of clouds, and they have lost orientation completely. Suddenly, the clouds part, and the two men see the top of a mountain with a man standing on it.

- "Hey! Can you tell us where we are?!"

The man doesn't reply. The minutes pass as the balloon drifts past the mountain. When the balloon is about to be swallowed again by the clouds, the man on the mountain shouts:

- "You're in a balloon!"
- "That must have been a mathematician."

The man astonished asks:

- "Why?"
- "First, he thought long and thoroughly about what to say. Second, what he eventually said was irrefutably correct. And last but not least... it was of no use whatsoever..."

An engineer, a mathematician, and a physicist are staying for the night in a hotel. Fortunately for this joke, a small fire out in each room.

- The physicist awakes, sees the fire, makes some careful observations, and on the back of the hotel's wine list does some quick calculations. Grabbing the fire extinguisher, he puts out the fire with one, short, well placed burst, and the crawls back into bed and goes back to sleep.
- The engineer awakes, sees the fire, makes some careful observations, and on the back of the hotel's room service list does some quick calculations. Grabbing the fire extinguisher (and adding a factor safety of 5), he puts out the fire by hosing down the entire room server times over, and then crawls into his soggy bed and goes back to sleep.
- The mathematician awakes, sees the fire, makes some careful observations, and on a blackboard installed in the room, does some quick calculations. Jubilant, he exclaims "A solution exists!", and crawls into his dry bed and goes back to sleep.

* * *

A doctor, a lawyer and a mathematician were discussing the relative merits of having a wife or a mistress.

- The lawyer says: "For sure a mistress is better. If you have a wife and want a divorce, it causes all sorts of legal problems.
- The doctor says: "It's better to have a wife because the sense of security lowers your stress and is good for your health.
- The mathematician says: "You're both wrong. It's best to have both so that when the wife thinks you're with the mistress and the mistress thinks you're with your wife... you can do some mathematics."

A prominent businessman hires a mathematician, a physicist and a computer scientist in order to win every horses competition.

- The mathematician go on the task, it computes matrices without end, define axioms at any headland and after long weeks of lemmas, theorems and conjectures, he concludes that the problem is formally unhearable.
- Then the computer scientist happy to see that the mathematician failed, is approaching its Cray III and after writing volumes of algorithms in C++ and introduced all the parameters and initial conditions joyfully announces that it will take just a few hundred years to calculate the result of each competition...
- The physicist, has a smile, he informs his distinguished colleagues that he has the solution. He approaches a blackboard and while drawing a sphere begins by saying: "approximate the horse by a perfect sphere..."

During a job interview, an entrepreneur receives four engineers: one who followed the Military Polytechnic School of Paris, the second HEC, the third is computer engineer, and the last followed University. It explains the four candidates in the end, to run a business, you just need to count.

He therefore addresses the first of them, the polytechnician, and said, "go ahead, count ..."

- The polytechnician: "one... two... one... two..."

The man surprised then asked the engineer who followed HEC: "To you! Count ..."

- The engineer of HEC: "one KiloDollar... two KiloDollar, three KD..."

He then turns anxiously toward the computer scientist: "To you! Count ..."

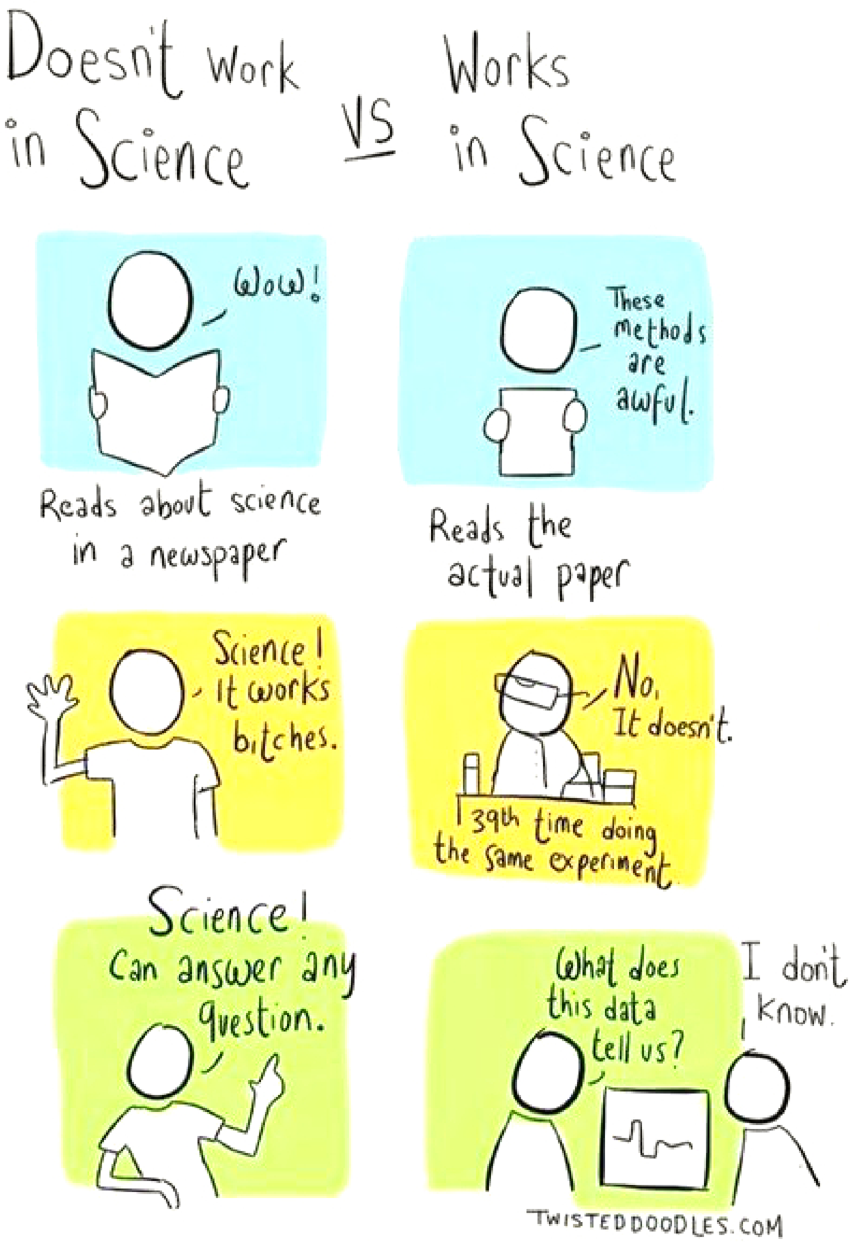
– The computer scientist: "0... 1... 0... 1..."

Desperate, the entrepreneur ask the engineer who followed University: "Go ahead, count ..."

– The young man begins: "1... 2... 3... 4... 5... 6... 7..."

The entrepreneur feeling reassured: "Continue, continue ..."

– "8... 9... 10... valet... lady.. king... " !!



Doesn't Work in Science
VS
Works in Science
Wow!
Reads about science in a newspaper
These methods are awful.
Reads the actual paper
Science! It works bitches.
No, It doesn't.
39th time doing the same experiment
Science! Can answer any question.
What does this data tell us?
I don't know.
TWISTEDDOODLES.COM

Several people were asked to solve the following problem: "Prove that all odd integers are prime."

- Mathematician: 3 is a prime, 5 is a prime, 7 is a prime, 9 is not a prime - counter-example - claim is false.
- Physicist: 3 is a prime, 5 is a prime, 7 is a prime, 9 is an experimental error, 11 is a prime ...
- Engineer: 3 is a prime, 5 is a prime, 7 is a prime, 9 is a prime, 11 is a prime ...
- Computer Scientist: 3's a prime, 5's a prime, 7's a prime ... segmentation fault
- Lawyers: one is prime, three is prime, five is prime, seven is prime, although there appears to be facing evidence that nine is not prime, there exists substantial precedent to indicate that nine should be considered prime. The following brief presents the case for nine's primeness...
- Liberals: The fact that nine is not prime indicates a deprived cultural environment which can only be remedied by a federally funded cultural enrichment program.
- Computer programmers: one is prime, three is prime, five is prime, five is prime, five is prime, five is prime five is prime, five is prime, five is prime...
- Professor: 3 is prime, 5 is prime, 7 is prime, and the rest are left as an exercise for the student.
- Linguist: 3 is an odd prime, 5 is an odd prime, 7 is an odd prime, 9 is a very odd prime,...
- Computer Scientist: 10 prime, 11 prime, 101 prime...
- Chemist: 1 prime, 3 prime, 5 prime... hey, let's publish!
- New Yorker: 3 is prime, 5 is prime, 7 is prime, 9 is... NONE OF YOUR DAMN BUSINESS!
- Programmer: 3 is prime, 5 is prime, 7 is prime, 9 will be fixed in the next release,...
- Salesperson: 3 is a prime, 5 is a prime, 7 is a prime, 9 – let me make you a deal...
- Advertiser: 3 is a prime, 5 is a prime, 7 is a prime, 11 is a prime,...
- Accountant: 3 is prime, 5 is prime, 7 is prime, 9 is prime, deducting 10% tax and 5% other obligations.
- Statistician: Let's try several randomly chosen numbers: 17 is a prime, 23 is a prime, 11 is a prime... Looks good to me.
- Psychologist: 3 is a prime, 5 is a prime, 7 is a prime, 9 is a prime but tries to suppress it...
- HR: What is a prime number? What is an odd integer?

A mathematician, an engineer and a physicist are given a red rubber ball to determine its volume.

- The mathematician: Measure the diameter and evaluates the triple integral.
- The physicist: Fill a tub of water, places the ball in water and measure the total displacement volume.
- The engineer: Search the model and serial number in its "red rubber balls" table.

The following concerns a question in a physics degree exam at the University of Copenhagen: "Describe how to determine the height of a skyscraper with a barometer."

One student replied:

"You tie a long piece of string to the neck of the barometer, then lower the barometer from the roof of the skyscraper to the ground. The length of the string plus the length of the barometer will equal the height of the building."

This highly original answer so incensed the examiner that the student was failed immediately. The student appealed on the grounds that his answer was indisputably correct, and the university appointed an independent arbiter to decide the case.

The arbiter judged that the answer was indeed correct, but did not display any noticeable knowledge of physics. To resolve the problem it was decided to call the student in and allow him six minutes in which to provide a verbal answer that showed at least a minimal familiarity with the basic principles of physics.

For five minutes the student sat in silence, forehead creased in thought. The arbiter reminded him that time was running out, to which the student replied that he had several extremely relevant answers, but couldn't make up his mind which to use. On being advised to hurry up the student replied as follows:

"Firstly, you could take the barometer up to the roof of the skyscraper, drop it over the edge, and measure the time it takes to reach the ground. The height of the building can then be worked out from the formula $H = 0.5g \cdot t^2$. But bad luck on the barometer."

"Or if the Sun is shining you could measure the height of the barometer, then set it on end and measure the length of its shadow. Then you measure the length of the skyscraper's shadow, and thereafter it is a simple matter of proportional arithmetic to work out the height of the skyscraper."

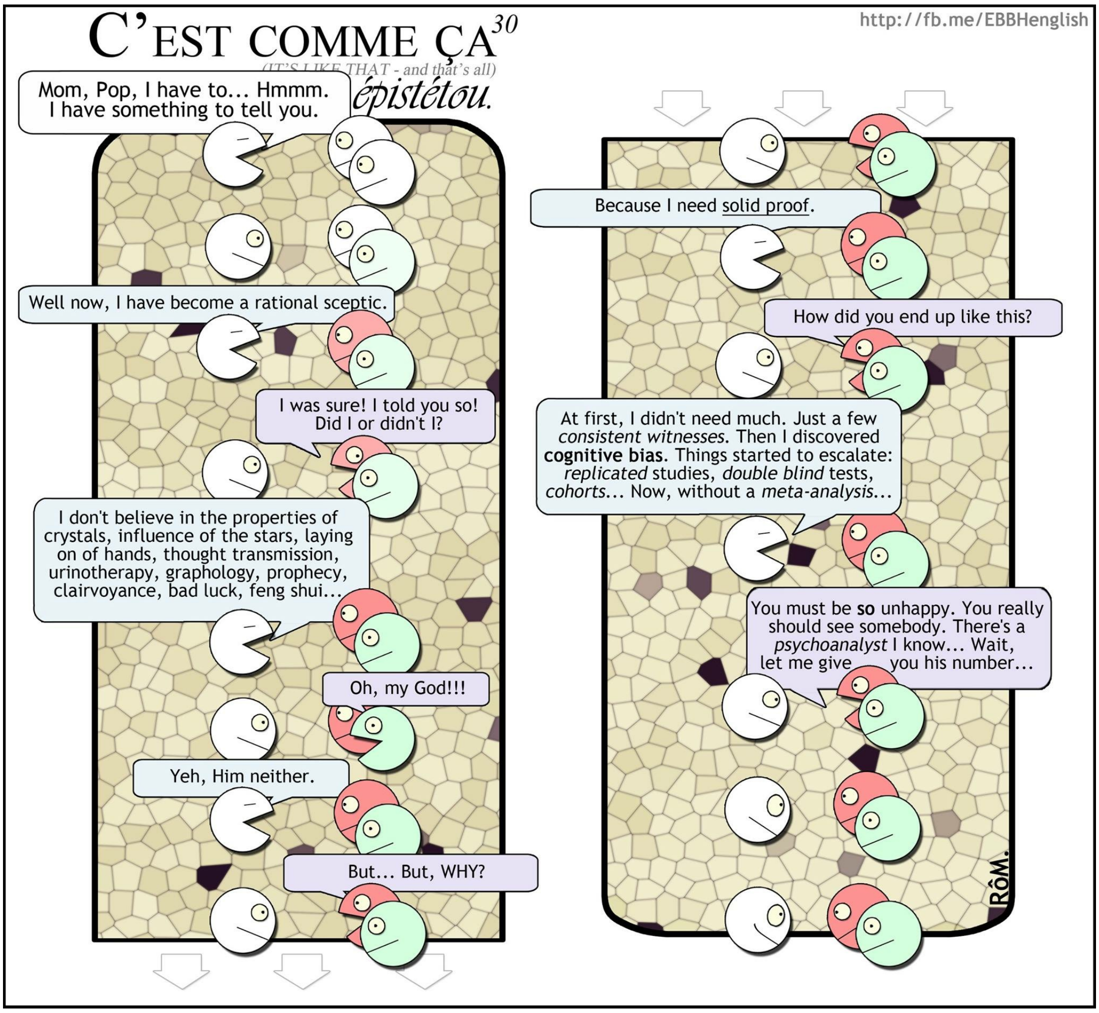
"But if you wanted to be highly scientific about it, you could tie a short piece of string to the barometer and swing it like a pendulum, first at ground level and then on the roof of the skyscraper. The height is worked out by the difference in the gravitational restoring force $T = 2\pi\sqrt{l/g}$."

"Or if the skyscraper has an outside emergency staircase, it would be easier to walk up it and mark off the height of the skyscraper in barometer lengths, then add them up."

"If you merely wanted to be boring and orthodox about it, of course, you could use the barometer to measure the air pressure on the roof of the skyscraper and on the ground, and convert the difference in millibars into feet to give the height of the building."

"But since we are constantly being exhorted to exercise independence of mind and apply scientific methods, undoubtedly the best way would be to knock on the janitor's door and say to him 'If you would like a nice new barometer, I will give you this one if you tell me the height of this skyscraper'."

The student was Niels Bohr (Nobel Prize 11923 according to holocene calendar), the only Dane to win the Nobel Prize for physics.



C'EST COMME ÇA[30]
(IT'S LIKE THAT - and that's all)
épistétou.

Mom, Pop, I have to... Hmmm. I have something to tell you.
Well now, I have become a rational sceptic.
I was sure! I told you so! Did I or didn't I?
I don't believe in the properties of crystals, influence of the stars, laying on of hands, thought transmission, urinotherapy, graphology, prophecy, clairvoyance, bad luck, feng shui...
Oh, my God!!!
Yeh, Him neither.
But... But, WHY?
Because I need solid proof.
How did you end up like this?
At first, I didn't need much. Just a few consistent witnesses. Then I discovered cognitive bias. Things started to escalate: replicated studies, double blind tests, cohorts... Now, without a meta-analysis...
You must be so unhappy. You really should see somebody. There's a psychoanalyst I know... Wait, let me give you his number...
RôM.

The story goes that Bertrand Russell, in a lecture logic, mentioned that in the sense of material implication, a false proposition implies any proposition. A student raised his hand and said:

- "In that case, given $2+2=5$, you can prove that you are the Pope"
- "Yes", answered Russell
- "And you could prove it now?!", asked the student sceptical
- "For sure!", said Russel who proposed immediately the following proof:
    1. Suppose that $2+2=5$
    2. Subtract 2 from the both side of the equality, we have $2=3$
    3. By symmetry, $3=2$
    4. Subtract 1 each side, we obtain, $2=1$
- Now the set containing just me and the Pope has 2 members. But $2=1$, so it has only 1 member; therefore, I am the Pope...

* * *

What is "pi"?

- Mathematician: "Pi is the ratio of the circumference of a circle to its diameter."
- Engineer: "Pi is about $22/7$."
- Physicist: "Pi is 3.14159 plus or minus 0.000005"
- Computer Programmer: "Pi is 3.141592653589 in double precision."
- Nutritionist: "You're one track math-minded fellows, Pie is a healthy and delicious dessert!"

* * *

An astronomer, a physicist, a mathematician and a computer scientist (it is said) were holidaying in Scotland. Glancing from a train window, they observed a black sheep in the middle of a field.

- "How interesting", observed the astronomer, "all scottish sheep are black!"
- To which the physicist responded: "No, no! Some Scottish sheep are black!"
- The mathematician gazed heavenward in supplication, and then intoned: "In Scotland there exists at least one field, containing at least one sheep, at least one side of which is black."

- The computer scientist: "Oh, no! A special case!"

A mathematician, a biologist and a physicist are sitting in a street coffee watching people going in and coming out of the house on the other side of the street.

First they see two people going into the house. Time passes. After a while they notice three persons coming out of the house.

- The physicist: "The measurement wasn't accurate."
- The biologists: "They have reproduced".
- The mathematician: "If now exactly one person enters the house then it will be empty again."

A mathematician and an engineer attend a lecture by a physicist. The topic concerns Kaluza-Klein theories involving physical processes that occur in spaces with dimensions of 9, 12 and even higher. The mathematician is sitting, clearly enjoying the lecture, while the engineer is frowning and looking generally confused and puzzled. By the end the engineer has a terrible headache. At the end, the mathematician comments about the wonderful lecture.

- The engineer says: "How do you understand this stuff?"
- Mathematician: "I just visualize the process."
- Engineer: "How can you visualize something that occurs in 9-dimensional space?"
- Mathematician: "Easy, first visualize it in n-dimensional space, then let n go to 9."

Two mathematicians are in a bar. The first one says to the second that the average person knows very little about basic mathematics. The second one disagrees, and claims that most people can cope with a reasonable amount of math.

The first mathematician goes off to the wash-room, and in his absence the second calls over the waitress. He tells her that in a few minutes, after his friend has returned, he will call her over and ask her a question. All she has to do is answer "one third x cubed."

She repeats "one thir – dex cue"?

He repeats "one third x cubed".

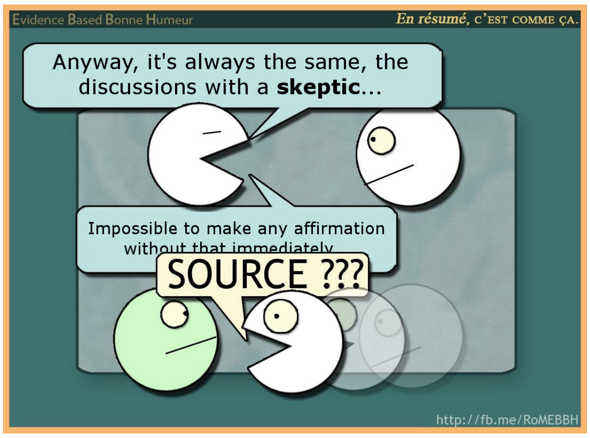
She asks, "one thir dex cuebd?"

"Yes, that's right," he says.

So she agrees, and goes off mumbling to herself, "one thir dex cuebd...".

The first guy returns and the second proposes a bet to prove his point, that most people do know something about basic math. He says he will ask the blonde waitress an integral, and the first laughingly agrees. The second man calls over the waitress and asks "what is the integral of x squared?".

The waitress says "one third x cubed" and while walking away, turns back and says over her shoulder "plus a constant!"



Evidence Based Bonne Humeur
En résumé, c'est comme ça.
Anyway, it's always the same, the discussions with a **skeptic**...
Impossible to make any affirmation without that immediately
SOURCE ???

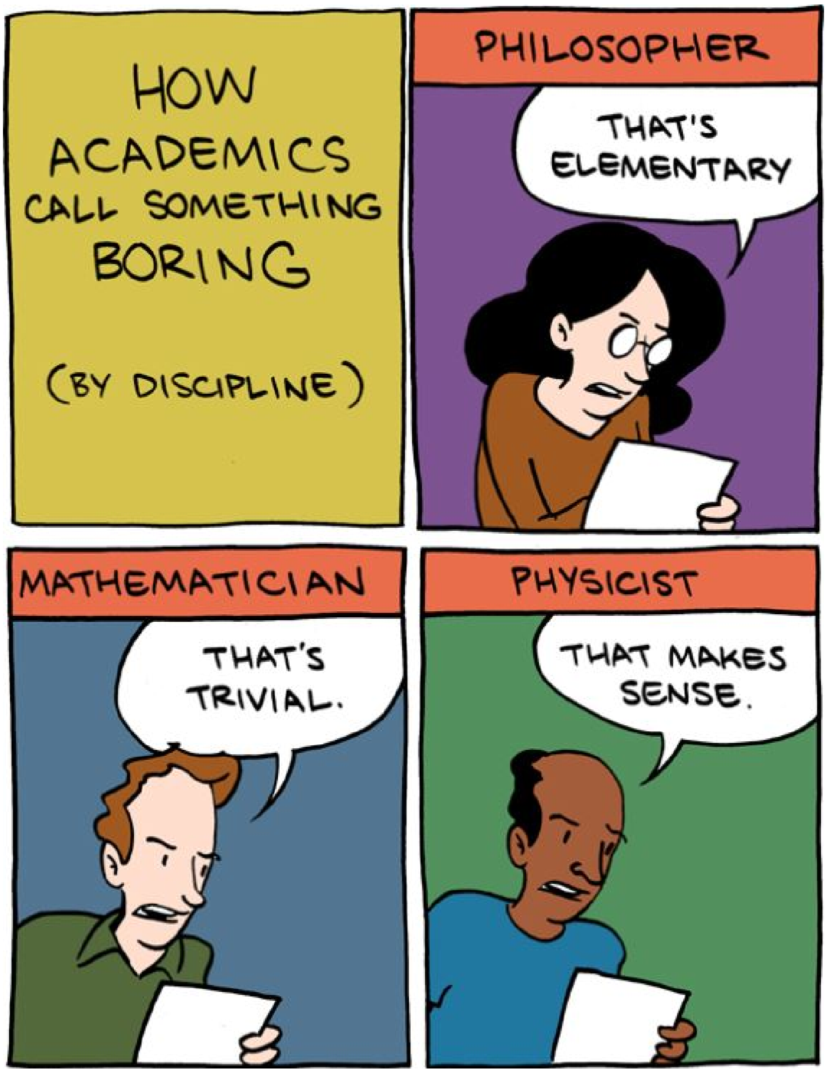
Teachers words:

- There are still pieces of the argument
- The '-' sign in front of the potential disturbs you? And if I put a '+' do you feel better? Yes! Then put a '+' ....
- This is a phase curve? No, this is a dog leg!
- Let's kill him and we will believe in suicide
- You can say it's predictable because it is unpredictable!
- I count on you to understand a little more thoroughly what will come next
- We will now study this a little later

- I will present you now some results dependent on Maxwell's equations that you have not seen yet ... anyway, at the point where we are ...
- If you do not understand, it's normal ... the contrary would be surprising indeed
- General relativity is useless! It is not with how we put satellites into orbit!
- Fifty cents question
- Occasionally, we have to be absurd
- When you have nothing to do, you take the Gauss theorem
- By which virtue of the Holy Spirit would it become neutral?!
- You will understand once you grow up...
- Take the example of a bank: there is a Mr. who makes a deposit and a Mrs. who makes withdrawal ... Finally, as usual what!
- ... more the parallelism will be parallel...
- Remove me these residues from earlier calculations
- Delete the left side. I said LEFT! Where is your right? This is ... Well the left is the other side!
- Ok, who will be the next victim?
- The '+' is recognized, and the electrons do not deceive themselves, for its beautiful red color!
- The goal is to verify that the test does not say shit
- If you can not do that, I assure you: it's all over for the exam
- If you can not do that, do it!
- You are very good at finding wrong things
- I like this kind of demonstration. You, it makes you have nightmares
- I won't will resolve this, as this may offend your sensibility!
- You must be careful with all what the teachers love!
- You add potatoes and pigs, it is dimensionless ...
- You can find the derivative of the Dirac pulse, it is not that we will jump to the head
- It's silly but Riemann, that's how
- Look at the equation that I just deleted
- Legally speaking, the current is in this sense

- There is no question that I waste my time to solve you this low fly joke!
- If the girl has understood then you must have all understood
- Oh yeah, you're laughing at me. In fact, you are right to make fun of us, because we do not hesitate to make fun of you
- Attention very important: I propose to dream at it on night
- I have the feeling of playing the Stradivarius before cows
- The hand of God spreads the field perpendicular to the surface
- The miracle of the disappearance of the harmonic will not happen today
- If you wake up at night, remember that sampling in the time domain is periodized in the frequency domain ... then you go back to sleep
- The left curves are not right
- You see, sometimes my results are correct
- We denote "Q" the output, it's obvious ...
- We'll have a trick to successfully recover this variable
- I am a 68000; Mr. Director comes in the corridor, knocking on the door: there is no better interruption!
- Warning: one, two, three, take your brains!
- In the steppes of automatic, we reach the arid part of mathematics
- What interest? Well no. This is a figure of speech Teaching
- If you have some memories of the signal flow graph that once we plotted ...
- The electrons in a hot metal, it's the New York main street at 5 in the evening, so it does not lead
- The circles, is what has the least corners!
- If you put your finger in a socket, it's not a complex number that comes
- See the proof in your daily readings ... So I waiver
- And then comes Carnot : he brings his mind that does not mean much
- Sometimes people who have a bit of culture that know that... it missed today!
- We will not name it "performance" because it can reach a value higher than 1, that might disturb some weak minds
- Me, if I had been sent to the blackboard, I would not have written this

- You will find the answer on www.archimedes.com
- I use a method that dates back several centuries ... as I do!
- Ask me questions ... I would like to have questions! ... other issues? I'll have to take the list and say: "But you have a question"!
- The ordering implemented depends on the instantiation of the garbage collector if it is synchronized to the preemptive multi-threading on the OS.
- You are only boxes receiving inputs and spitting outputs



HOW ACADEMICS CALL SOMETHING BORING
(BY DISCIPLINE)
PHILOSOPHER
THAT'S ELEMENTARY
MATHEMATICIAN
THAT'S TRIVIAL.
PHYSICIST
THAT MAKES SENSE.

Where is there mainly only religious holidays and not science holidays?

Answer: Because science always works!

Sherlock Holmes and Dr. John Watson went on a camping trip. After sharing a good meal and a bottle of Petri wine, they retire to their tent for the night.

At about 3 AM, Holmes nudges Watson and asks, "Watson, look up into the sky and tell me what you see?"

Watson said, "I see millions of stars."

Holmes asks, "And, what does that tell you?"

Watson replies, "Astronomically, it tells me there are millions of galaxies and potentially billions of planets. Astrologically, it tells me that Saturn is in Leo. Theologically, it tells me that God is great and we are small and insignificant. Horologically, it tells me that it's about 3 AM. Meteorologically, it tells me that we will have a beautiful day tomorrow. What does it tell you, Holmes?"

Holmes retorts, "Someone stole our tent."

An engineer, a mathematician, and a physicist are staying for the night in a hotel. Fortunately for this joke, a small fire breaks out in each room.

The physicist awakes, sees the fire, makes some careful observations, and on the back of the hotel's wine list does some quick calculations. Grabbing the fire extinguisher, he puts out the fire with one, short, well placed burst, and then crawls back into bed and goes back to sleep.

The engineer awakes, sees the fire, makes some careful observations, and on the back of the hotel's room service list (pizza menu) does some quick calculations. Grabbing the fire extinguisher (and adding a factor of safety of 5), he puts out the fire by hosing down the entire room several times over, and then crawls into his soggy bed and goes back to sleep.

The mathematician awakes, sees the fire, makes some careful observations, and on a blackboard installed in the room, does some quick calculations. Jubilant, he exclaims "A solution exists!", and crawls into his dry bed and goes back to sleep.

How do you know that the driver driving toward you is a physicist?

He has a red sticker on his bumper, saying: "If this sticker is blue, you are driving too fast."

A Princeton plasma physicist is at the beach when he discovers a ancient looking oil lantern sticking out of the sand. He rubs the sand off with a towel and a genie pops out. The genie offers to grant him one wish. The physicist retrieves a map of the world from his car and circles the Middle East and tells the genie, "I wish you to bring peace in this region".

After 10 long minutes of deliberation, the genie replies, "Gee, there are lots of problems there with Lebanon, Iraq, Israel, and all those other places. This is awfully embarrassing. I've never had to do this before, but I'm just going to have to ask you for another wish. This one is just too much for me".

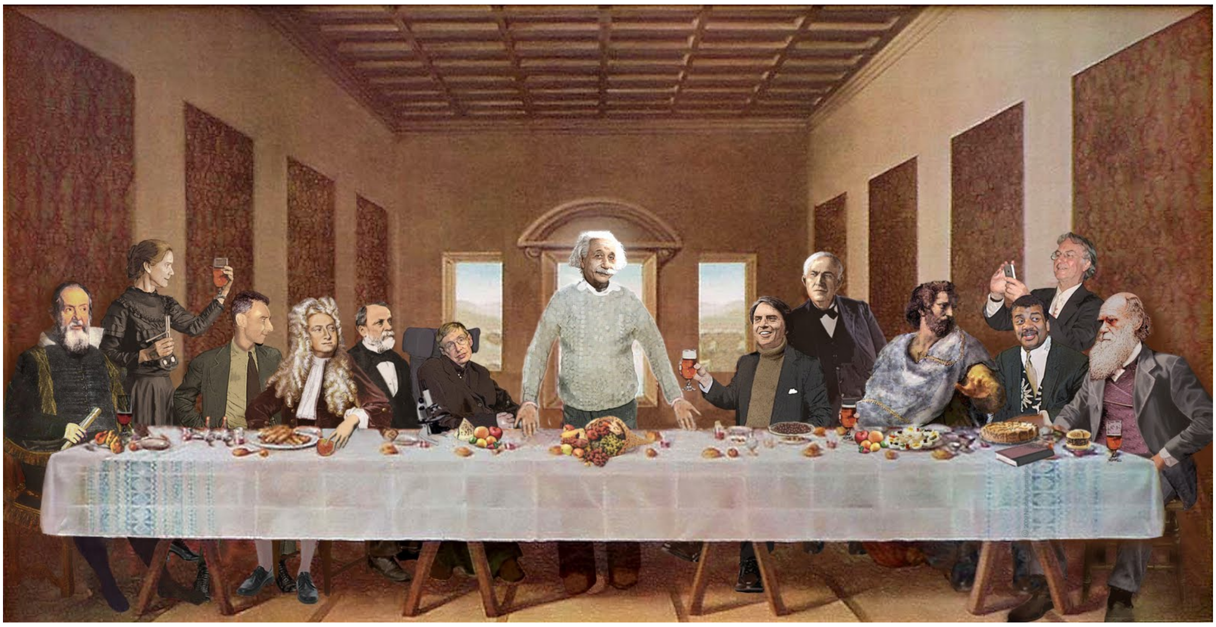
Taken aback, the physicist thinks a bit and asks, "I wish that the Princeton tokamak would achieve scientific fusion energy break-even."

After another deliberation the genie asks, "Could I see that map again?"

In the beginning, there were two species of apple trees: those whose apples fell, and those whose apples were rising. The apples that fell could reach the ground, germinate and so generating a new tree whose apples fell. But the rising apples never reached the ground, and species of apple trees with apples rising quickly disappeared because they could not reproduce. As they were not adapted, nature has thus eliminated. That's natural selection. If apples fall, it is thanks to natural selection!

But there are clever people who will object that the stones fall too. But they are not living beings, so they are not subject to natural selection, it is obvious. So the above explanation does not explain what happens to stones. In fact, for the stones, it is even simpler:

In the beginning, there were indeed two kinds of stones: those who fell, and who were rising. But those who raised up gone very far. That's why all the stones that remain on Earth do the same thing: they fall.



20.2. Mathematics

5 out of 4 people don't understand fractions...

Love is like π, natural, irrational, transcendent and very real.

A math teacher explains to a blonde the limits. He made it with the following exercise:

$$\lim_{x \to 8} \frac{1}{x-8} = +\infty$$

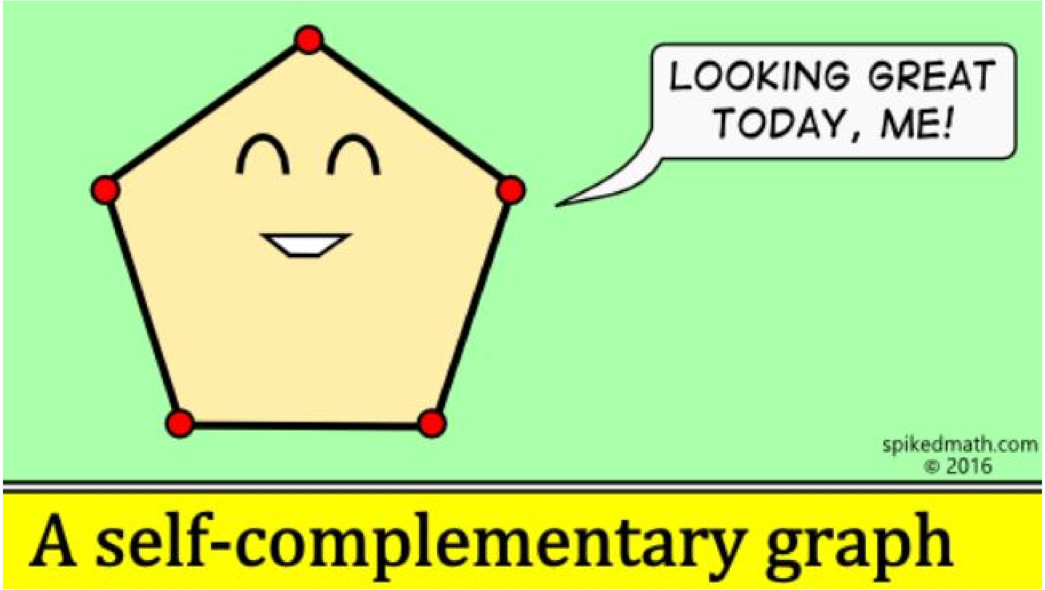
At the end of the exercise, he asked the blonde if she understood. "Oh yes sir I understood everything". Believing the answer only half, the teacher asked the following exercise:

Calculate:

$$\lim_{x \to 5} \frac{1}{x-5}$$

The blonde wrote:

$$\lim_{x \to 8} \frac{1}{x-8} = +\infty \quad \text{then} \quad \lim_{x \to 5} \frac{1}{x-5} = \rotatebox{90}{5}$$



LOOKING GREAT TODAY, ME!

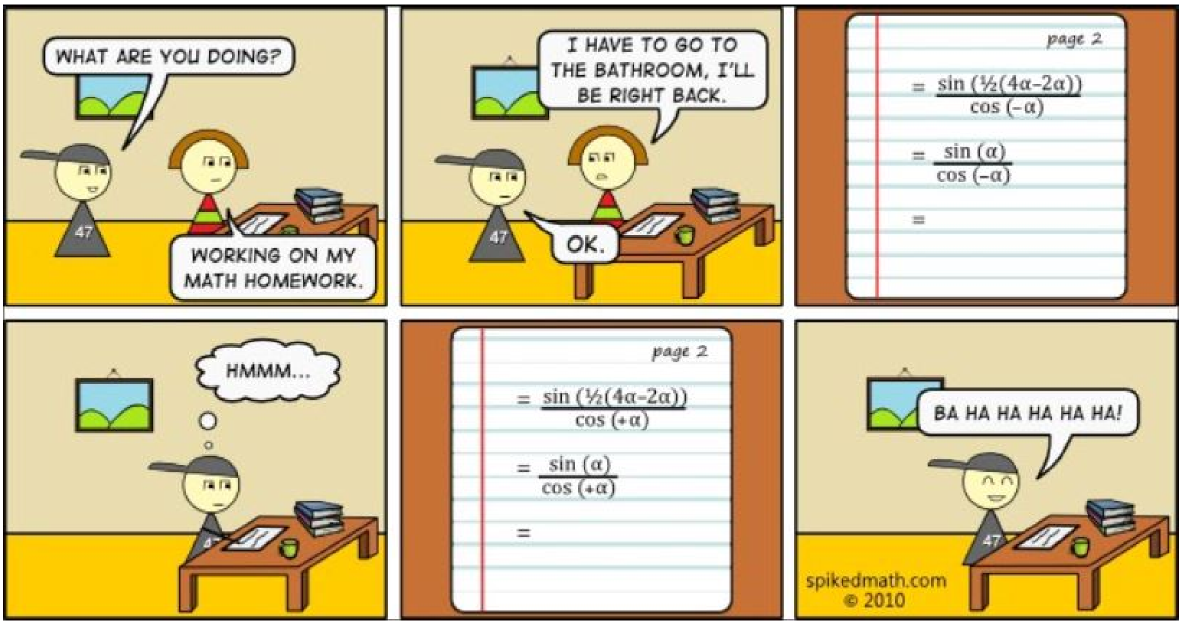
A self-complementary graph

Evolution of the teaching of Mathematics (...)

- Education 11960 (holocene calendar): A farmer sells a bag of potatoes for 100$. Its production costs amounted to 4/5 of the selling price. What is his profit?
- Traditional Education 11970 (holocene calendar): A farmer sells a bag of potatoes for 100$. Its production costs amounted to 4/5 of the selling price, that is to say 80$. What is his profit?
- Modern Education 11970 (holocene calendar): A farmer exchanges a set P of potatoes against a set M of money. The cardinality of the set M is 100, and each PFM element is 1$. Draw 100 large dots elements of the set M. The set F of the production costs are 20 big points less than the set M. Represent the set F as a subset of the set M and give the answer to the question: What is the cardinality of the set B benefits? (draw it in red)
- Renovated Education in 11980 (holocene calendar): A farmer sells a bag of potatoes for 100$. Production costs amount to 80$ and the benefit is 20$. Homework: underline the words "Potatoes" and discussed this with your neighbour.
- Start-up Education 11999 (holocene calendar): A wired producer of agricultural space consults a data bank which display the day-rate of the potato. It load its reliable software computation and determines the cash flow on bit-map screen (under config WMil with 40GB HDD and floppy). Draw with your mouse the integrated 3D contour of the bag of potatoes. Then log yourself to the network by www.blue-potatoe.com and follow the instructions of the menu.
- Education 12010 (holocene calendar): What is a farmer?



WHAT ARE YOU DOING?

When you read or listen	What you have to understand
this is trivial (or obvious)	i can not say why this is true
we get automatically	idem
a calculation shows that	a calculation that I did not will certainly show that
the reader will easily control that	it bothers me to show that
we strongly recommend the reader to make the indicated exercises	as I have not made them, you could correct me
i showed this result in a previous paper	i have absolutely no idea how I did to prove that thing
is easily generalized to	the generalization is beyond my level
according to a well known property	known by maximum 10 people in the world
the proof is in two lines	yes, but through five lemmas
it's algebra	it is not interesting (in the mouth of an analyst)
it's analysis	it is not interesting (in the mouth of an algebrist)
it's elementary (or classical)	in bornitziens space theory bornitziens of the second kind
i did not understand this step in your demonstration	you're stuck in your demo
this conference was very interesting	i did not understand anything

A mathematician to his friend:

- "Are you faithful?"
- "Yes, up to isomorphism"

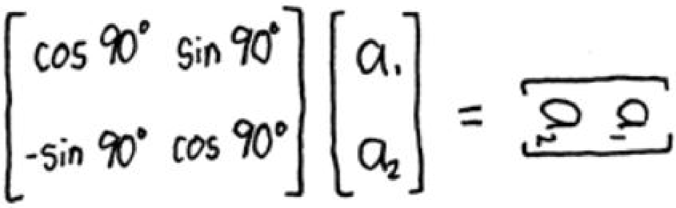
How mathematicians do it...:

- Algebraists do it by symbolic manipulation.
- Algebraists do it in a ring, in fields, in groups.
- Analysts do it continuously and smoothly.
- Applied mathematicians do it by computer simulation.
- Banach spacers do it completely.
- Bayesians do it with improper priors.
- Catastrophe theorists do it falling off part of a sheet.
- Combinatorists do it as many ways as they can.
- Complex analysts do it between the sheets
- Computer scientists do it depth-first.
- Cosmologists do it in the first three minutes.
- Decision theorists do it optimally.
- Functional analysts do it with compact support.
- Galois theorists do it in a field.
- Game theorists do it by dominance or saddle points.
- Geometers do it with involutions.
- Geometers do it symmetrically.
- Graph theorists do it in four colors.
- Hilbert spacers do it orthogonally.

- Large cardinals do it inaccessibly.
- Linear programmers do it with nearest neighbours.
- Logicians do it by choice, consistently and completely.
- Logicians do it incompletely or inconsistently.
- (Logicians do it) or [not (logicians do it)].
- Number theorists do it perfectly and rationally.
- Mathematical physicists understand the theory of how to do it, but have difficulty obtaining practical results.
- Pure mathematicians do it rigorously.
- Quantum physicists can either know how fast they do it, or where they do it, but not both.
- Real analysts do it almost everywhere
- Ring theorists do it non-commutatively.
- Set theorists do it with cardinals.
- Statisticians probably do it.
- Topologists do it openly, in multiply connected domains
- Variationists do it locally and globally.
- Cantor did it diagonally.
- Fermat tried to do it in the margin, but couldn't fit it in.
- Galois did it the night before.
- Mðbius always does it on the same side.
- Markov does it in chains.
- Newton did it standing on the shoulders of giants.
- Turing did it but couldn't decide if he'd finished.

What will a complex French guy said to a real woman?

Answer: "viens danser !" (you have to read "come in C", the complex set...)



Two-way sentences in French and English:

- We solve now this problem without complex
- Un repère d'origine O (un repaire d'originaux...)
- Une partie de $\mathbb{Q}$ (a fucking party...)
- Ne confondez pas un ρ avec un p... (don't confuse between a fart and a burp)
- Une variété de Poisson... (a variety of fish)

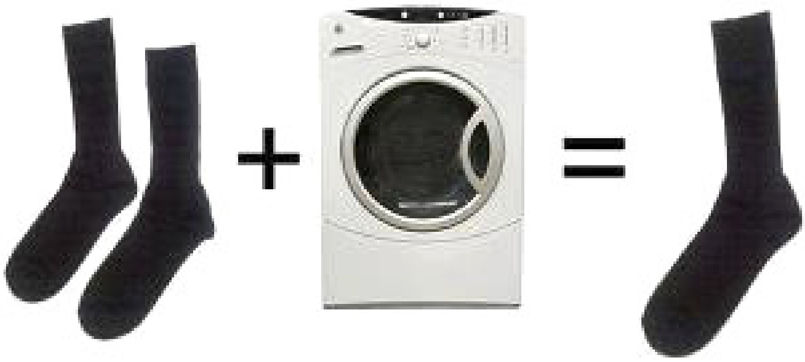
Logarithm and exponential functions are at the restaurant. When comes the addition, which will pay?

Answer: Exponential, because logarithme né paie rien (in English "neperien" phonetically means: pay nothing)

Later in the evening, Logarithm and Exponential go home a little bit drunk. Logarithm asks: Do I drive?

Exponential answers: I'd rather it be me who leads. In the case you derivate...

Two Cauchy sequences want to go out to dance. They arrive at a club where the "No Limit" evening event takes place. They decide to enter, but the guard stops them, saying, "Sorry, we're complete" (in a complete space, a Cauchy sequence is convergent by definition, so it has a limit).



A mathematician went fool and believed that he was the differentiation operator. His friends had placed him in a mental hospital until he got better. All day he would go around frightening the other patients by staring at them and saying: "I differentiate you!"

One day he met a new patient; and true to form he stared at him and said "I differentiate you!", but for once, his victim's expression didn't change. Surprised, the mathematician marshalled his energies, stared fiercely at the new patient and said loudly "I differentiate you!", but still the other man had no reaction. Finally, in frustration, the mathematician screamed out "I DIFFERENTIATE YOU!"

The new patient calmly looked up and said: "You can differentiate me all you like: I'm e to the x."

What mathematicians say and what you have to understand:

- Trivial: If I have to show you this, you're in the wrong class
- One can trivially show: We do not need more than 4 hours to write the proof
- Check yourself: This is the hard part of the demonstration so you can do on your spare time
- Similarly: At least one line of the proof is identical to the previous
- Proceed formally: We will manipulate symbols with many predefined rules without understanding the real meaning of the result.

- We will provide us the proof: Trust me, it's true!
- The reader will easily show: I get tired to show that...
- We strongly suggest the reader to make the indicated exercises: As I have not made them, you could correct me
- I showed this result in a previous paper: I do not know how the devil did to prove this thing
- We generalize easily: The generalization is beyond my level
- According to a well known property: For 10 people in the world ...

There are 3 kinds of people: those who can count and those who can not count...

Everyone knows the "Salary Theorem" which states that engineers and scientists can NEVER earn as much as businessmen and commercial. This theorem can then be demonstrated by solving a simple math equation.

Our equation is based on two well known postulates:

P1. The Knowledge is Power

P2. Time is Money:

All engineers know that:

$$\text{Power} = \frac{\text{Work}}{\text{Time}}$$

and:

$$\text{Knowledge} = \text{Power}$$

and also:

$$\text{Time} = \text{Money}$$

We then obtain by substitution:

$$\text{Knowledge} = \frac{\text{Work}}{\text{Money}}$$

And we finally get the following result:

$$\text{Money} = \frac{\text{Work}}{\text{Knowledge}}$$

So when the Knowledge approaches zero, Money approaches infinity regardless of the value attributed to work, this value may be very low. Conversely when Knowledge goes to infinity, the Silver tends to zero, even if the work is high value.

Hence the obvious conclusion follows: The less you know, the more money you make.

PS: Those of you who have had some difficulty understanding this should be the highest paid.

■ Q.E.D.

HMMM...
TWO HOURS LATER...
AH YES, IT'S TRIVIAL!

In the same kind here is the "misogynistic theorem":

First, we state that girls factorable variables in amounts of time and money such as:

$$\text{Girls} = \text{Time} \times \text{Money}$$

As we all know "time is money". So:

$$\text{Time} = \text{Money}$$

and because "money is the root of evil ...":

$$\text{Money} = \sqrt{\text{Evil}}$$

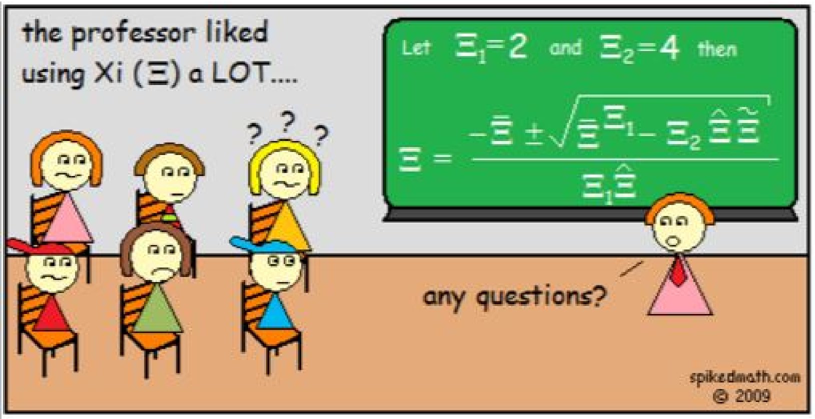
Then we have by substitution:

$$\text{Girls} = \left(\sqrt{\text{Evil}}\right)^2$$

We are therefore forced to conclude:

$$\text{Girls} = \text{Evil}$$

■ Q.E.D.



the professor liked using Xi (Ξ) a LOT....
Let $\Xi_1=2$ and $\Xi_2=4$ then
$\Xi = \frac{-\Xi \pm \sqrt{\Xi^{\Xi_1} - \Xi_2 \hat{\Xi} \tilde{\Xi}}}{\Xi_1 \hat{\Xi}}$
? ? ?
any questions?

The top ten excuses for not doing your math homework:

#10. Galileo didn't know calculus; what do I need it for?

#09. A math addict stole my homework.

#08. I'm taking physics and the homework in there seemed to involve math, so I thought I could just do that instead.

#07. I have the proof, but there isn't room to write it in the margin.

#06. I have a solar powered calculator and it was cloudy.

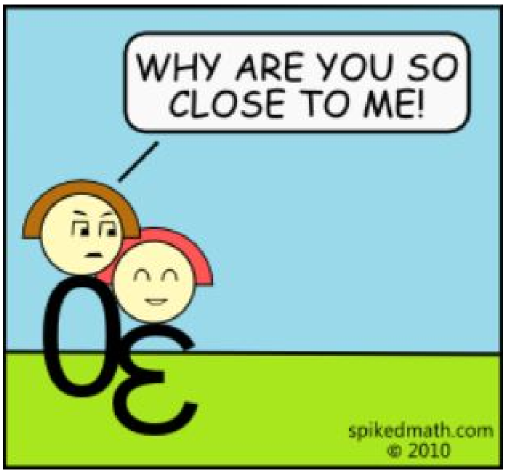
#05. I was watching the World Series and got tied up trying to prove that it converged.

#04. I could only get arbitrarily close to my textbook. (I reached half way, and then half of that, and then ...)

#03. I couldn't figure out whether i am the square root of negative one or i is the square root of negative one.

#02. It was Einstein's birthday and pi day and we had this big celebration! (This only works for March 14)

#01. I accidentally divided by zero and my paper burst into flames.



WHY ARE YOU SO CLOSE TO ME!

What is the result of:

$$\frac{2ab}{2Fr.16}$$

(read "2 abbés sur 2 françaises")

Answer:

$$2bb\frac{a}{e}$$

(read "2 bébés assurés")

What is the result of:

$$\frac{\text{cheval}}{\text{oiseau}}$$

(read "horse on bird")

As we have:

$$\frac{\text{cheval}}{\text{oiseau}}=\frac{\text{vache}\cdot 1}{\beta\cdot 1}$$

(read "vache + l" (contains all letters of the word "cheval") divided by "bête à ailes" meaning animal with wing)

But:

$$\frac{\text{vache}\cdot 1}{\beta\cdot 1}=\frac{\beta\cdot\pi\cdot 1}{\beta\cdot 1}$$

(read "bête à pie + l" divided by "bête à ailes")

We simplify to get:

$$\frac{\cancel{\beta}\cdot\pi\cdot\cancel{1}}{\cancel{\beta}\cdot\cancel{1}}=\pi$$

This proves that π is irrational because there is no rational comparison between a "cheval" (horse) and an "oiseau" (bird)...

We have to prove that:

$$\frac{\text{ROSSINI}}{\text{SOLSIDO}}=1$$

We can write this as following:

$$\frac{\text{ROS SI NI}}{\text{SOL SI DO}}=\frac{\text{ROS NI}}{\text{SOL DO}}$$

but "NI vaut Do" (in French this means "niveau d'eau" or in English "water level") thus:

$$\frac{\text{ROS}}{\text{SOL}}$$

But "SOL fait RINO" (Solferino: it's during this battle that Henri Dunant had the idea to create the Red Cross) then:

$$\frac{\text{ROS}}{\text{RI NO}}$$

because "RINO c'est ROS" (rhinocéros) then RINO = ROS and we finally have:

$$\frac{\text{ROS}}{\text{ROS}}=1$$

A DAY IN THE LIFE OF AN EIGENVECTOR
WATCH THIS...
A
λ
x
YO, A, COME HERE!
spikedmath.com © 2010
WHAT'S UP GUYS?
HEHEHE
HMM...
I FEEL STRANGE.
I'M GOING TO GO NOW.
BAHAHAHAHA!
WAY TO "SCALAR".

Each future engineer learns to write the sum of two rational numbers, for example:

$$1+1=2$$

This form is however rather banal and indicates gaps in your education.

In the first semester, we learn that:

$$1=\ln(e)$$

and:

$$1=\sin^2(p)+\cos^2(q)$$

Also everybody know that:

$$2=\sum_{n=0}^{+\infty}\left(\frac{1}{2}\right)^n$$

and that therefore the equation:

$$1+1=2$$

can be written more simply:

$$\ln(e)+\sin^2(p)+\cos^2(q)=\sum_{n=0}^{+\infty}\left(\frac{1}{2}\right)^n$$

we must admit that the look is much clearer and more scientific...

On the other hand, it is clear that:

$$1=\cosh(q)\sqrt{1-\tanh^2(q)}$$

and also:

$$e=\lim_{z\to+\infty}\left(1+\frac{1}{z}\right)$$

it follows that:

$$\ln(e)+\sin^2(p)+\cos^2(q)=\sum_{n=0}^{+\infty}\left(\frac{1}{2}\right)^n$$

can be rewritten as follows:

$$\ln\left(\lim_{z\to+\infty}\left(1+\frac{1}{z}\right)\right)+\sin^2(p)+\cos^2(q)=\sum_{n=0}^{\infty}\left(\frac{\cosh(q)\sqrt{1-\tanh^2(q)}}{2}\right)^n$$

We must also remember that:

$$0!=1$$

and the inverse exponent of the exponent is opposite equal to the exponent of the exponent opposite. Assuming an n-dimensional space, we know that:

$$\left(X^T\right)^{-1}-\left(X^{-1}\right)^{-T}=0$$

Taking the matrix as the metric of an oriented and orthogonal canonical space:

$$\left(g_{ij}^T\right)^{-1}-\left(g_{ij}^{-1}\right)^{-T}=0$$

logically we obtain:

$$\left(\left(g_{ij}^T\right)^{-1}-\left(g_{ij}^{-1}\right)^{-T}\right)!=1$$

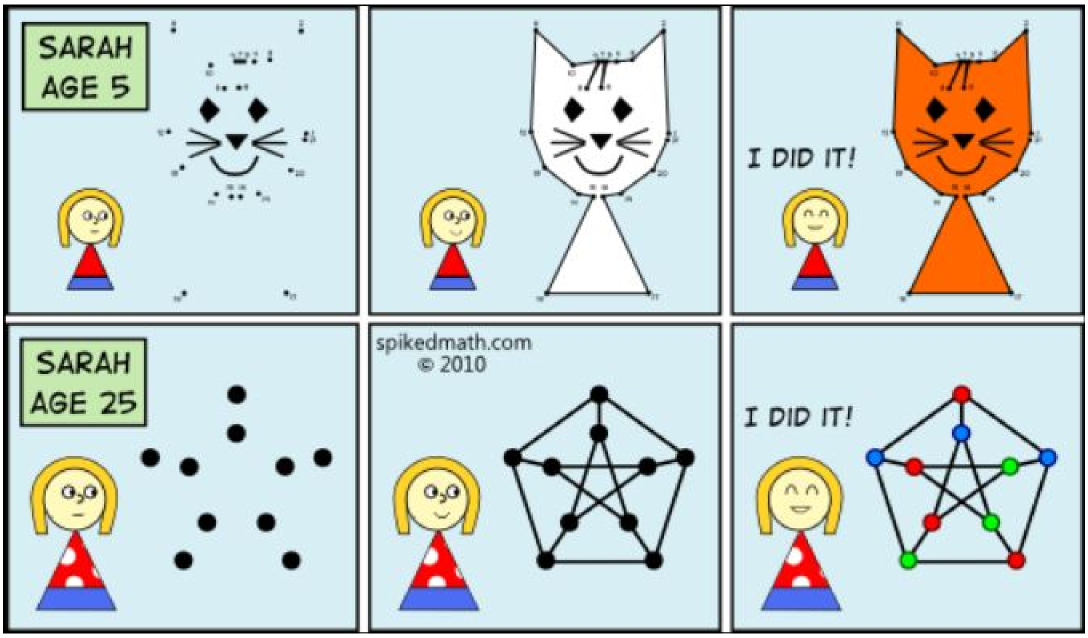
we get a simple and clear expression of $1+1=2$ for everyone:

$$\ln\left(\lim_{z\to+\infty}\left(\left(\left(g_{ij}^T\right)^{-1}-\left(g_{ij}^{-1}\right)^{-T}\right)!+\frac{1}{z}\right)\right)+\sin^2(p)+\cos^2(q)=\sum_{n=0}^{+\infty}\left(\frac{\cosh(q)\sqrt{1-\tanh^2(q)}}{2}\right)^n$$

It is therefore obvious that this equation is much more understandable than:

$$1+1=2$$

It would be possible to show several other developments of this simple expression and we will do from the moment you begin to understand the simple principles of the previous method.

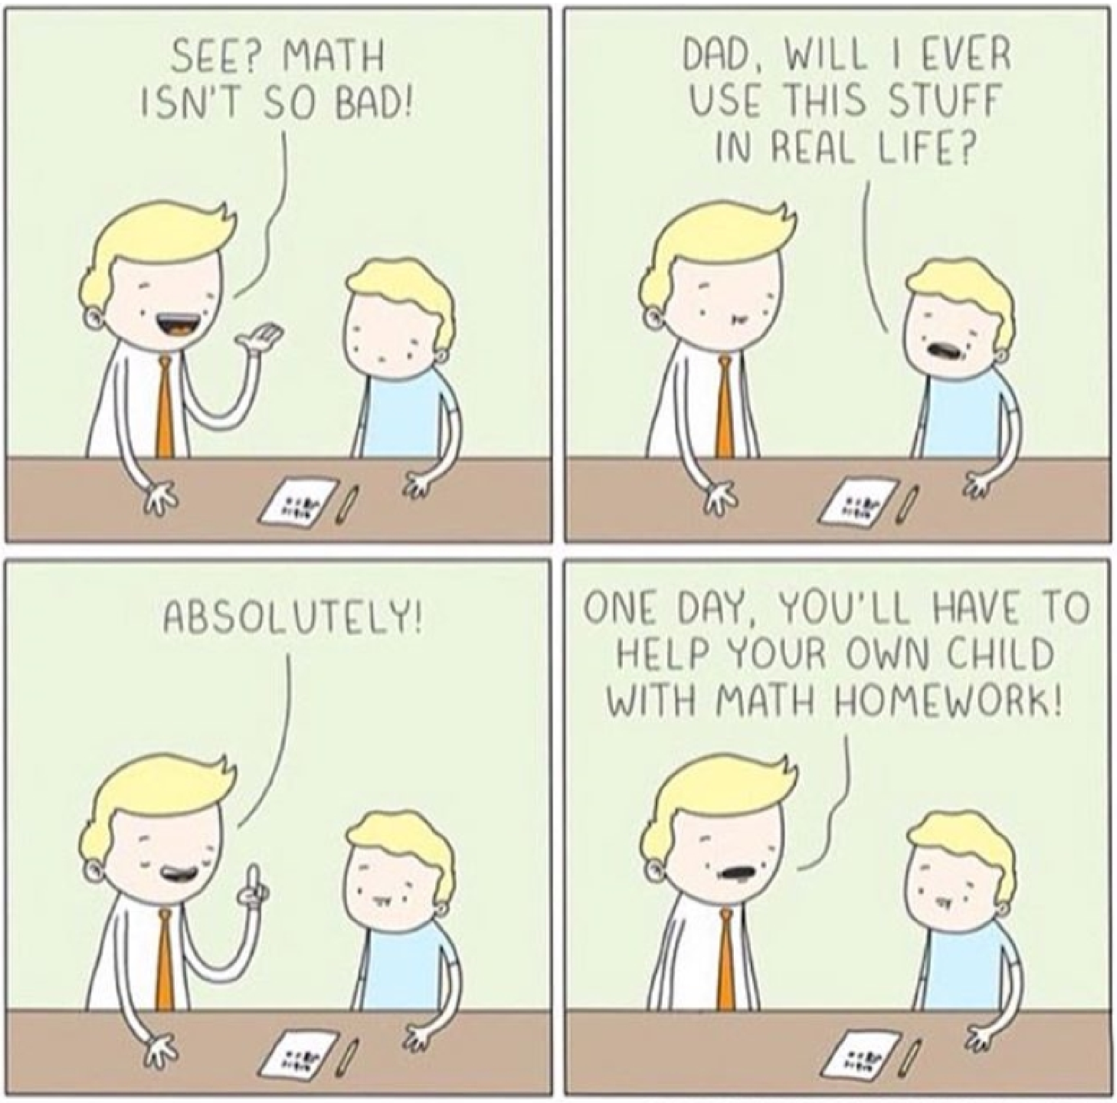


A wrestler, a physicist and a mathematician are subject to an experience: they are locked in a room each with a box of spinach, closed, and no can opener. After 24 hours, we'll see what they have become.

- The wrestler was able to open her box, "Well, I just flung violently the box against the wall. The impact was such that it is open", he explains.
- The physicist also managed to open her box: "I watched the box, and distinguished his break points. I then performed a pressure to exert maximum force on them, and the box was naturally open."
- The mathematician, finally, is found prostrate in a corner of the room, the sweat streaming down his face, and his box, closed, between the feet: "We admit that the box is opened ... We admit that... ".

Why we write d instead of d for the differential operator:

$$\frac{\cancel{d}}{\cancel{d}x}x=\frac{1}{\cancel{x}}\cancel{x}=1$$



SEE? MATH ISN'T SO BAD!
DAD, WILL I EVER USE THIS STUFF IN REAL LIFE?
ABSOLUTELY!
ONE DAY, YOU'LL HAVE TO HELP YOUR OWN CHILD WITH MATH HOMEWORK!

THEGENTLEMANSARMCHAIR.COM

Mathematics of life:

$$\begin{array}{lcr} & \text{Life} + \text{Love} = & \text{Happy} \\ + & \text{Life - Love} = & \text{Sad} \\ \hline \text{2Life} & = & \text{Happy+Sad} \end{array}$$

Therefore:

$$\text{Life} = \frac{\text{Happy} + \text{Sad}}{2}$$

Developing:

$$\text{Life} = \frac{1}{2}\text{Happy} + \frac{1}{2}\text{Sad}$$

That's real Life. Enjoy it!

An opinion without 3.14 is an onion. You'll understand!

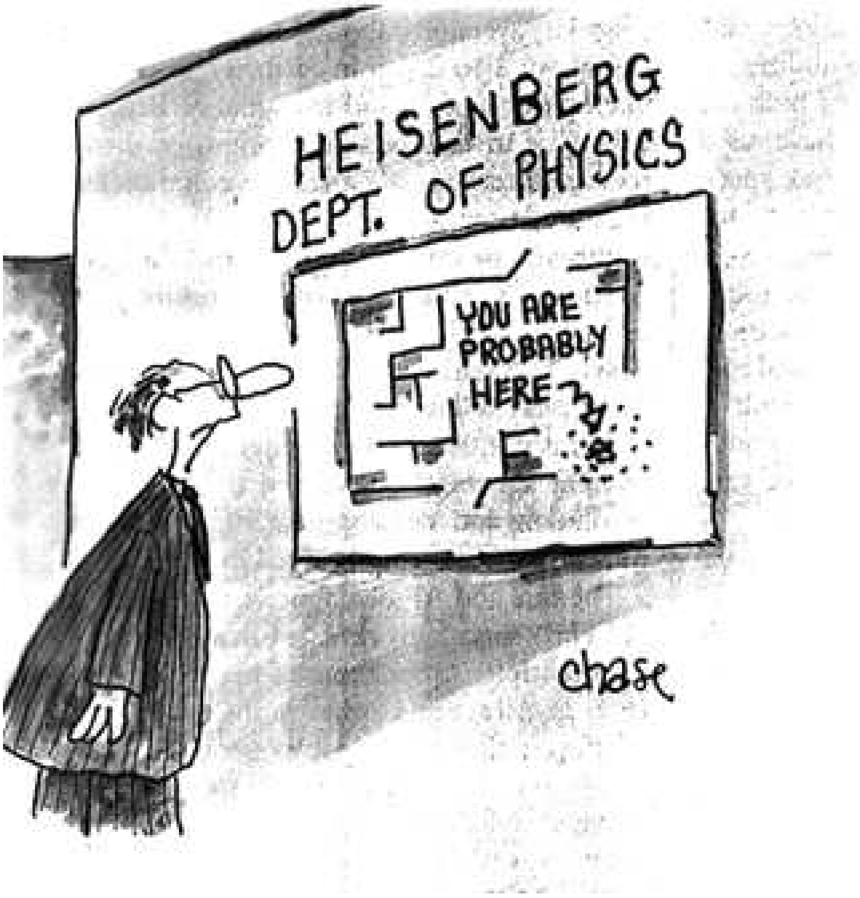
20.3. Physics



- In theory, there is no difference between theory and practice. In practice, there is a difference!
- The theory is when we know everything but nothing works. The practice is when everything works, but we do not know why. In computer science, theory and practice are met: nothing works and you do not know why!

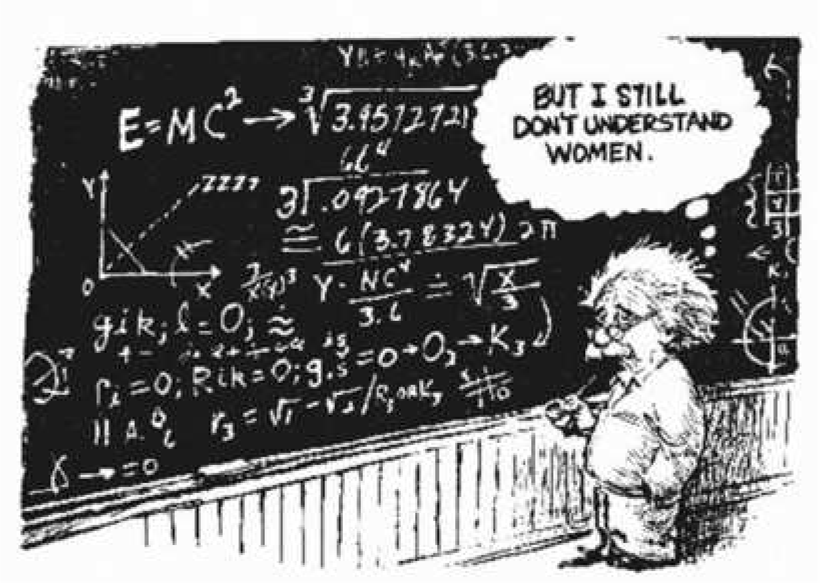
- Matter is fundamentally lazy - It always takes the path of least effort.
- Matter is fundamentally stupid - It tries every other path first.
- That is the heart of physics - The rest is details!

Two atoms meets together.

One says to the other: "Shit, I lost an electron!"

The other: "Are you sure?"

And the first replies, "POSITIVELY!!"



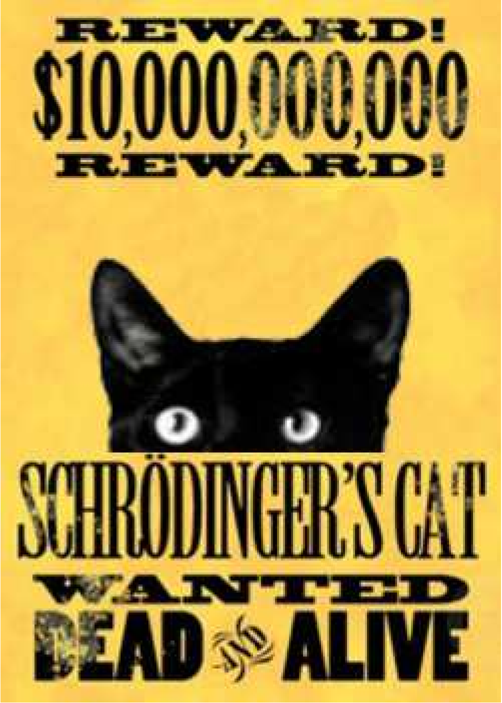
BUT I STILL DON'T UNDERSTAND WOMEN.
E=MC²

You enter the laboratory and see an experiment. How will you know which class is it?

- If it's green and wiggles, it's biology.
- If it stinks, it's chemistry.
- If it doesn't work, it's physics.

Theorem: A cat has nine tails.

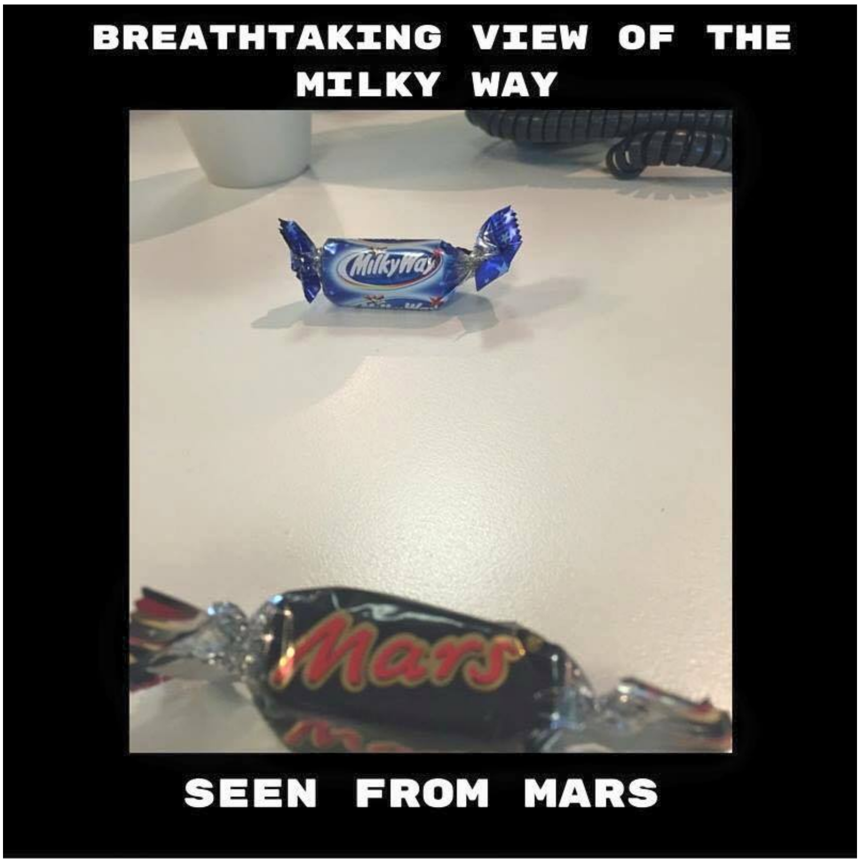
Proof: No cat has eight tails. A cat has one tail more than no cat. Therefore, a cat has nine tails.



A physicist studying quantum physics, is someone who does not see very well, looking in a dark room for a black cat, who probably does not exist.

An engineer, a physicist, a mathematician, and a mystic were asked to name the greatest invention of all times.

- The engineer chose fire, which gave humanity power over matter.
- The physicist chose the wheel, which gave humanity the power over space.
- The mathematician chose the alphabet, which gave humanity power over symbols.
- The mystic chose the thermos bottle.
  "Why a thermos bottle?" the others asked.
- The mystic: "Yes, because the thermos keeps hot liquids hot in winter and cold liquids cold in summer."
- "Yes... so what?" the others asked.
- The mystic: "Think about it." said the mystic reverently. "That little bottle.. how does it know?"



Physics professor has been doing an experiment, and has worked out an empirical equation that seems to explain his data. He asks the math professor to look at it.

A week later, the math professor says the equation is invalid. By then, the physics professor has used his equation to predict the results of further experiments, and he is getting excellent results, so he asks the math professor to look again.

Another week goes by, and they meet once more. The math professor tells the physics professor the equation does work, "But only in the trivial case where the numbers are real and positive".

Practical nuclear fusion power plants are just 30 years away - and always will be.

This is how scientists see the world.

Heisenberg was driving down the highway whereupon he was pulled over by a policeman.

The policeman asked:

- "Do you know how fast you were going back there?"

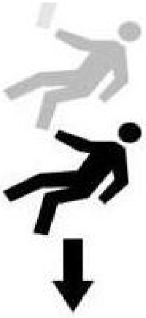
Heisenberg replied:

- "No, but I know where I am."

What's the difference between an auto mechanic and a quantum mechanic?

The quantum mechanic can sometimes get the car inside the garage without opening the door.

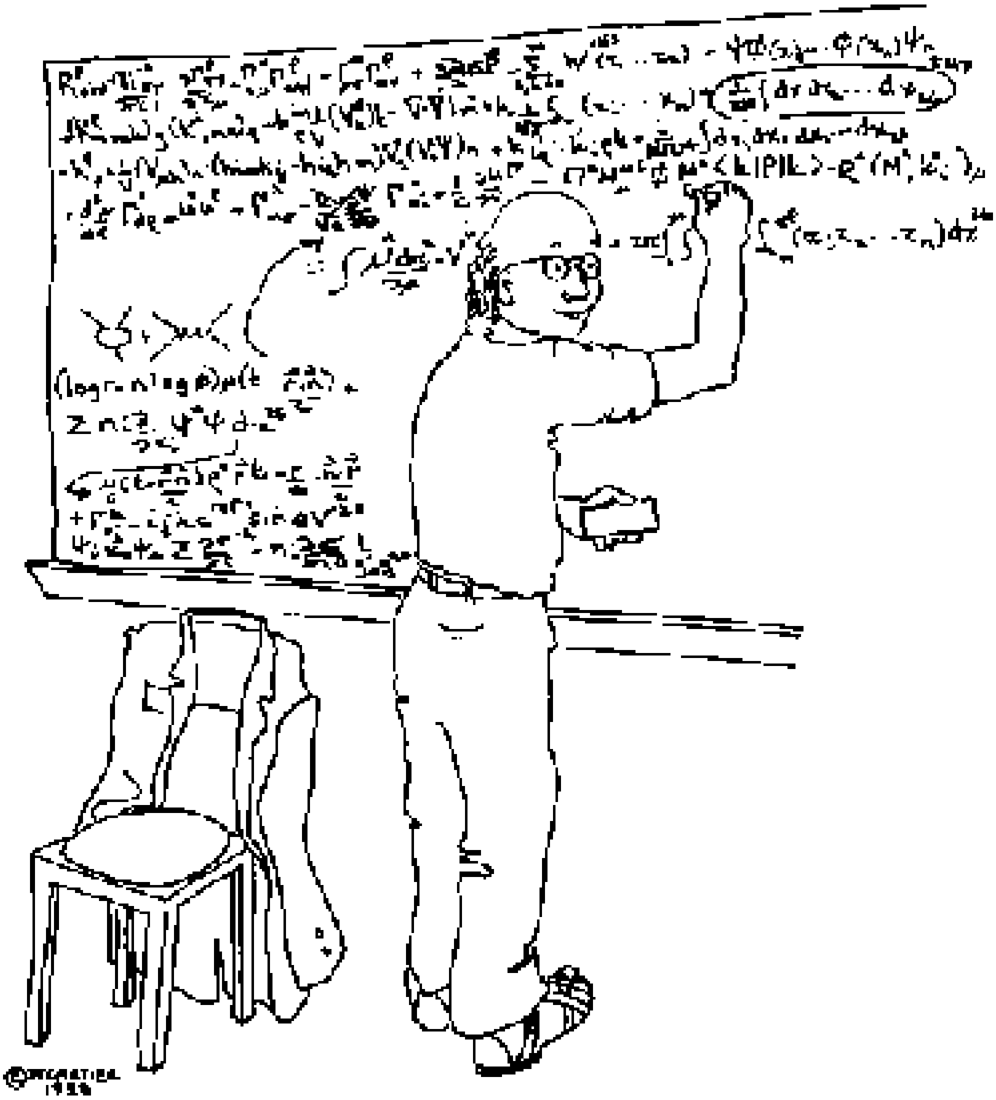
It's not the:



$$v_f = v_0 + at$$

that kills you, it's the:

$$F = m\frac{\Delta v}{\Delta t}$$

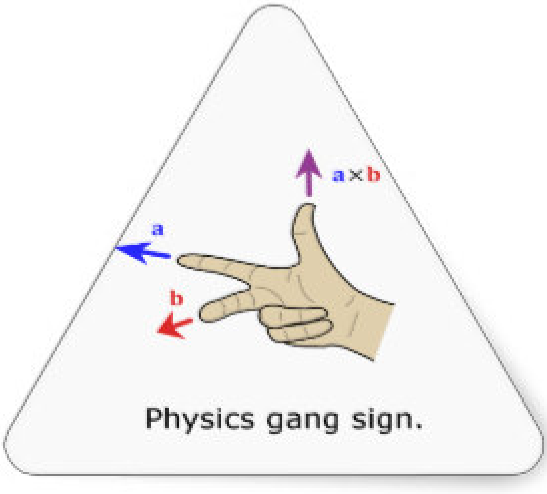


"At this point we notice that this equation is beautifully simplified if we assume that space–time has 92 dimensions."

Why God never received tenure at any University:

1. He had only one major publication.
2. It was in Hebrew.
3. It had no references.
4. It wasn't published in a refereed journal.
5. Some even doubt he wrote it himself.

6. It may be true that he created the world, but what has he done since then?
7. His cooperative efforts have been quite limited.
8. The scientific community has had a hard time replicating his results.
9. He never applied to the Ethics Board for permission to use human subjects.
10. When one experiment went awry he tried to cover it up by drowning the subjects.
11. When subjects didn't behave as predicted, he deleted them from the sample.
12. He rarely came to class, just told students to read the Book.
13. Some say he had his son teach the class.
14. He expelled his first two students for learning.
15. Although there were only ten requirements, most students failed his tests.
16. His office hours were infrequent and usually held on a mountaintop.



In the beginning there was Aristotle:

- And objects at rest tended to remain at rest
- And objects in motion tended to come to rest
- And God saw that it was boring, although very restful.

Then God created Newton:

- And objects at rest tended to remain at rest
- And objects in motion tended to remain in motion
- And energy was conserved, and momentum was conserved,
- And matter was conserved
- And God saw that it was conservative.

Then God created Einstein:

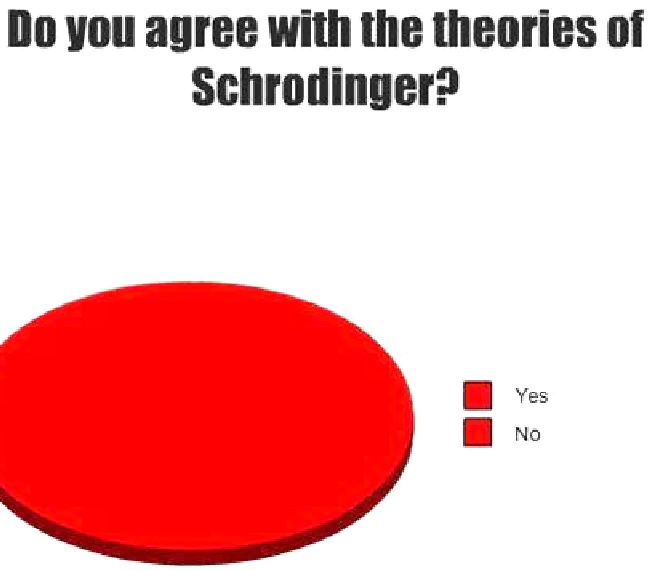
- And everything was relative
- And fast things became short
- And straight things became curved
- And the universe was filled with inertial frames
- And God saw that it was relatively general but some of it was especially relative.

Then God created Bohr:

- And there was the principle
- And the principle was quantum
- And all things were quantified
- But some things were still relative
- And God saw that it was confusing.

Then God was going to create Furgeson:

- And Furgeson would have unified
- And he would have fielded a theory
- And all would have been one.
- But it was the seventh day
- And God rested
- And objects at rest tend to remain at rest.

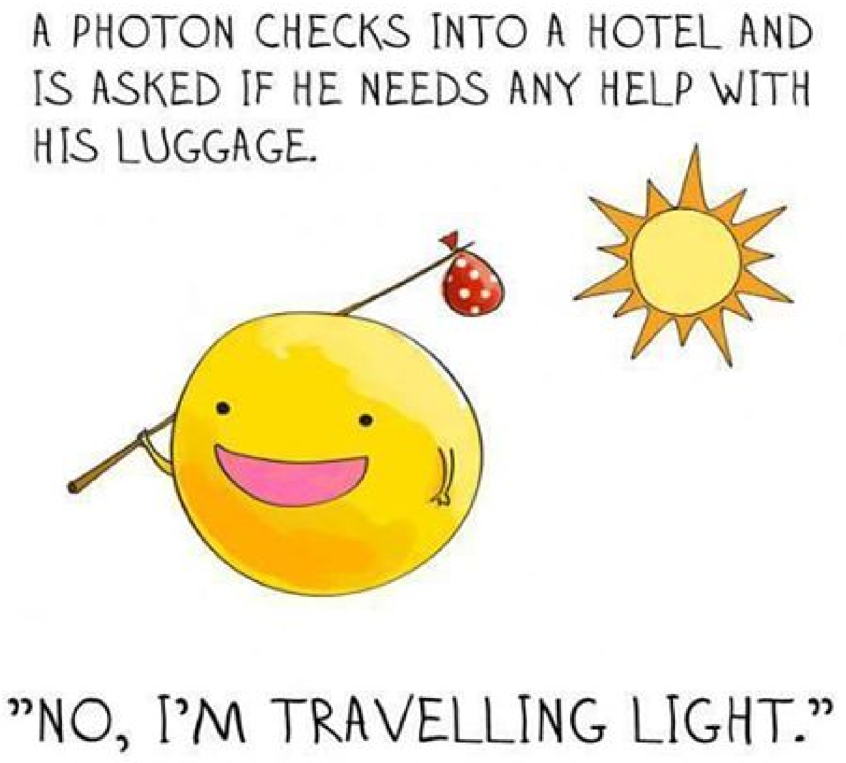


The Physicist's Bill of Rights

We hold these postulates to be intuitively obvious, that all physicists are born equal, to a first approximation, and are endowed by their creator with certain discrete privileges, among them a mean rest life, n degrees of freedom, and the following rights which are invariant under all linear transformations:

1. To approximate all problems to ideal cases.
2. To use order of magnitude calculations whenever deemed necessary (i.e. whenever one can get away with it).
3. To use the rigorous method of "squinting" for solving problems more complex than the addition of positive real integers.

4. To dismiss all functions which diverge as "nasty" and "unphysical".
5. To invoke the uncertainty principle when confronted by confused mathematicians, chemists, engineers, psychologists, dramatists, and other lower scientists.
6. hen pressed by non-physicists for an explanation of (4) to mumble in a sneering tone of voice something about physically naive mathematicians.
7. To equate two sides of an equation which are dimensionally inconsistent, with a suitable comment to the effect of, "Well, we are interested in the order of magnitude anyway".
8. To the extensive use of "bastard notations" where conventional mathematics will not work.
9. To invent fictitious forces to delude the general public.
10. To justify shaky reasoning on the basis that it gives the right answer.
11. To cleverly choose convenient initial conditions, using the principle of general triviality.
12. To use plausible arguments in place of proofs, and thenceforth refer to these arguments as proofs.
13. To take on faith any principle which seems right but cannot be proved.



A PHOTON CHECKS INTO A HOTEL AND IS ASKED IF HE NEEDS ANY HELP WITH HIS LUGGAGE.
"NO, I'M TRAVELLING LIGHT."

You can at least take this simple "Real Scientist Quiz" to find out if you're cut out for the life of a true scientist:

1. At Christmas time, you:
   a. Take a couple of days off to spend time with your family.
   b. Leave early on Christmas eve so you can pick up a few presents for the family.
   c. Only work half a day, spending the rest of the day at home working on your grant application.
2. Your spouse wants to discuss plans for the family vacation with your kids. You:
   a. Propose to go camping so you can explain the wonders of nature to your kids.
   b. Propose to go to another city so you can spend the day in your friend's lab while your spouse takes the kids sightseeing.
   c. Ask your spouse, "We have kids?"
3. At a scientific meeting on an island in the South Pacific, no talks are scheduled in the afternoon. During this free time, you:
   a. Follow the local custom and sunbathe on the beach in the nude.
   b. Sit on the beach fully clothed, unaware of the nude sunbathers, and discuss science with your colleagues.
   c. Sit in your hotel room with the drapes closed, and work on your manuscript.
4. The nurse at school calls to tell you that your second-grade child has chicken pox. You:
   a. Immediately drop what you're doing and rush to school to pick up your sick kid.
   b. Immediately drop what you're doing and begin trying to find a cure for chicken pox.
   c. Ask the nurse for directions to the school, and the names of your kids.
5. Beings from outer space visit Earth, and you are the first human they meet. To show their friendship, they present you with a highly advanced device that is capable of prolonging life, ending human suffering, and curing disease. You:
   a. Present it to the United Nations.
   b. Apply for a patent.
   c. Break it open to see how it works.
6. What is the longest amount of time that you have worked without a vacation (excluding scientific meetings)?
   a. Six months.
   b. Two years.
   c. I took a weekend off about 10 years ago.
7. What are your hobbies?

   a. Sports, music, and dance, because they allow the analytical parts of my brain to relax.
   b. Cooking, because it’s quite a lot like science.
   c. Reading back issues of scientific journals cover to cover.

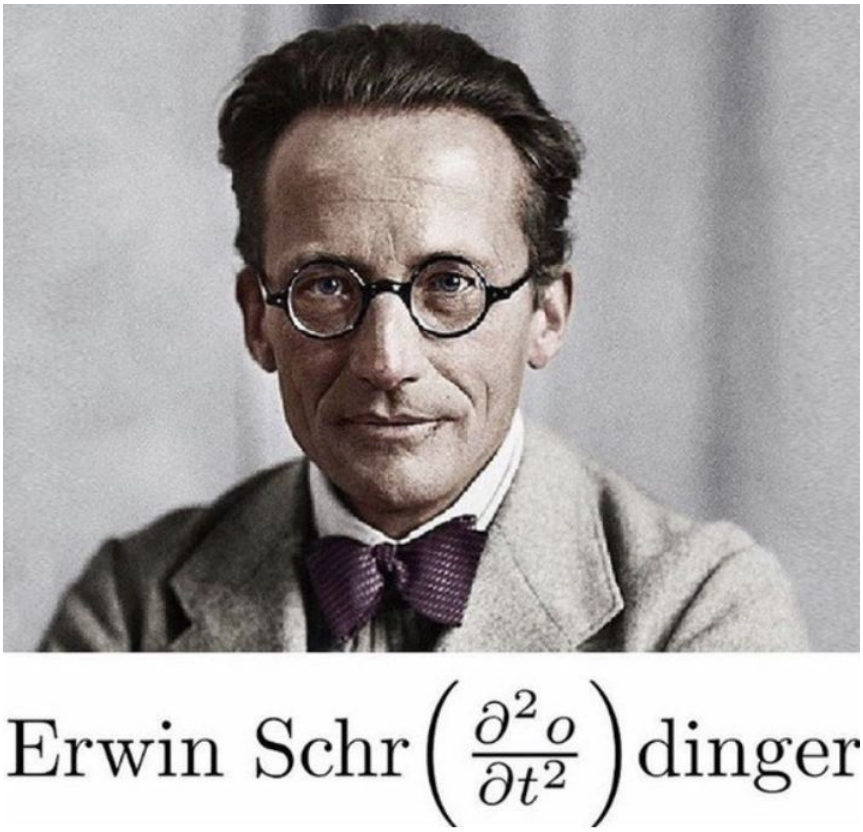
8. Your best friend is:

   a. A member of your college fraternity.
   b. A member of your immediate family.
   c. A member of a gene family.

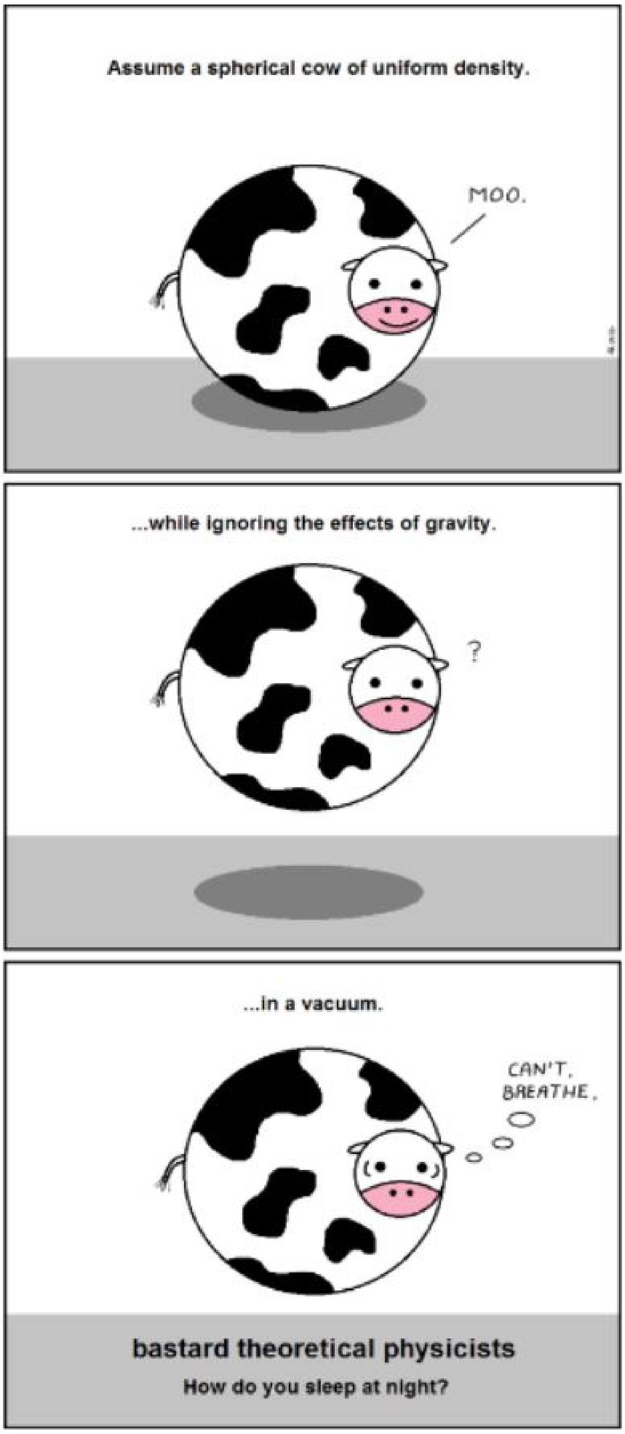
Score:

Give yourself 1 point for every question you answered with an "a", 5 points for every "b" and 50 points for every "c". If you took the test three times and averaged your score, give yourself 100 extra points. If you calculated the standard error of the mean, give yourself 500 points.

If you scored less than 10, you are normal. Scores of 11-50 indicate an obsessed scientist. If you scored more than 50, you are in need of help and should consider joining *Scientists Anonymous*; if you scored greater than 500, you should forget *Scientists Anonymous* and get back to work since you are beyond help, and may actually succeed as a scientist.



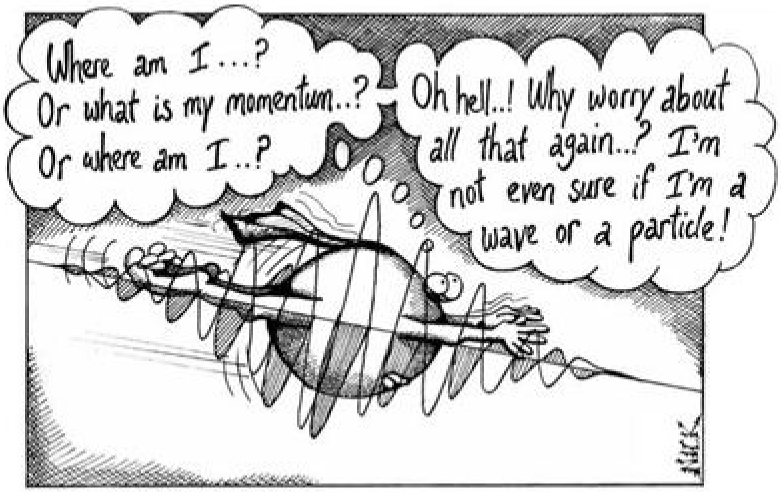
Erwin Schr$\left(\frac{\partial^2 o}{\partial t^2}\right)$dinger



Assume a spherical cow of uniform density.
MOO.
...while ignoring the effects of gravity.
?
...in a vacuum.
CAN'T. BREATHE.
bastard theoretical physicists
How do you sleep at night?

How you must understand certain sentences in physicists publications of:

- It is well known that...: I did not read the references, but..
- This is of great theoretical importance: This is important for me.
- Though it was not possible to give a definitive answer: The experiment failed, but it seems me valuable enough to write a publication.
- The used technique was particularly appropriate ...: The lab next door friend had already developed the technique.
- 3 samples were chosen for an exhaustive study: The results obtained from other samples yielded nothing coherent.
- Handled with extreme caution throughout the experiment: Was not thrown down the trash.
- The agreement with theory is excellent: it is passable.
- The agreement with theory is good: it is weak.
- The agreement with theory is satisfactory: it is doubtful.
- The agreement with theory is fair: it is totally imaginary.
- It is generally accepted that...: two colleagues agree with me
- It is recognized that: I think.
- It is clear that further work will be useful: I did not understand anything.
- Here are some typical results: Here are the best results.
- Significant in a confidence interval of...: not significant.
- The reagents used were synthesized in the laboratory according to standardized techniques: The reagents were purchased from...
- Unfortunately, quantitative basis to exploit the results have not yet been made: Nobody was able to understand anything of what was observed.
- We are grateful to X for his valuable collaboration and Y for the fruitful discussions: X and Y did the work and told me what the results meant.



Where am I...? Or what is my momentum..? Or where am I..?
Oh hell..! Why worry about all that again..? I'm not even sure if I'm a wave or a particle!
HACK

An experimental physicist performs an experiment involving two cats, and an inclined tin roof.

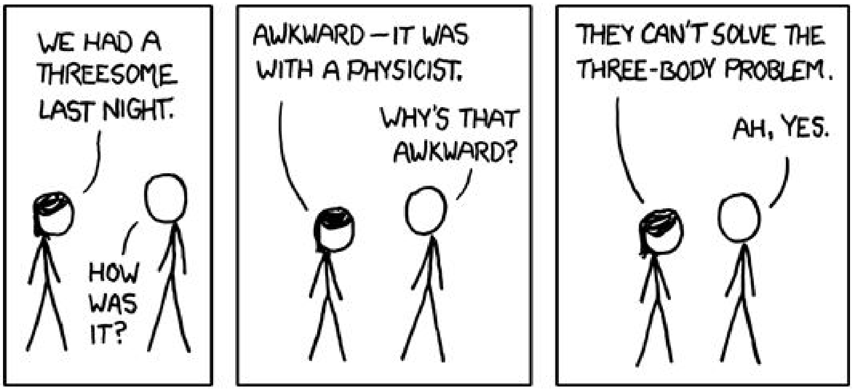
The two cats are very nearly identical; same sex, age, weight, breed, eye and hair color.

The physicist places both cats on the roof at the same height and lets them both go at the same time.

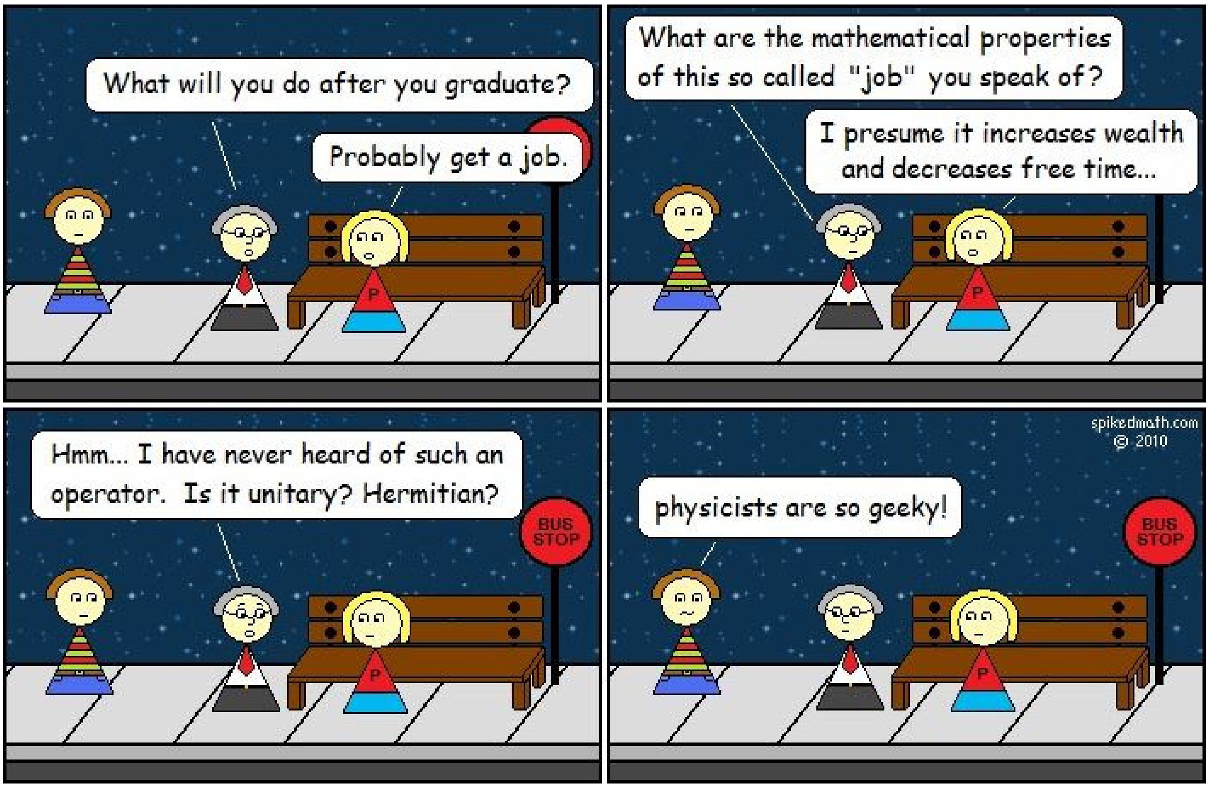
One of the cats fall off the roof first so obviously there is some difference between the two cats.

What is the difference?

One cat has a greater mew!



WE HAD A THREESOME LAST NIGHT.
HOW WAS IT?
AWKWARD – IT WAS WITH A PHYSICIST.
WHY'S THAT AWKWARD?
THEY CAN'T SOLVE THE THREE-BODY PROBLEM.
AH, YES.



What will you do after you graduate?
Probably get a job.
What are the mathematical properties of this so called "job" you speak of?
I presume it increases wealth and decreases free time...
Hmm... I have never heard of such an operator. Is it unitary? Hermitian?

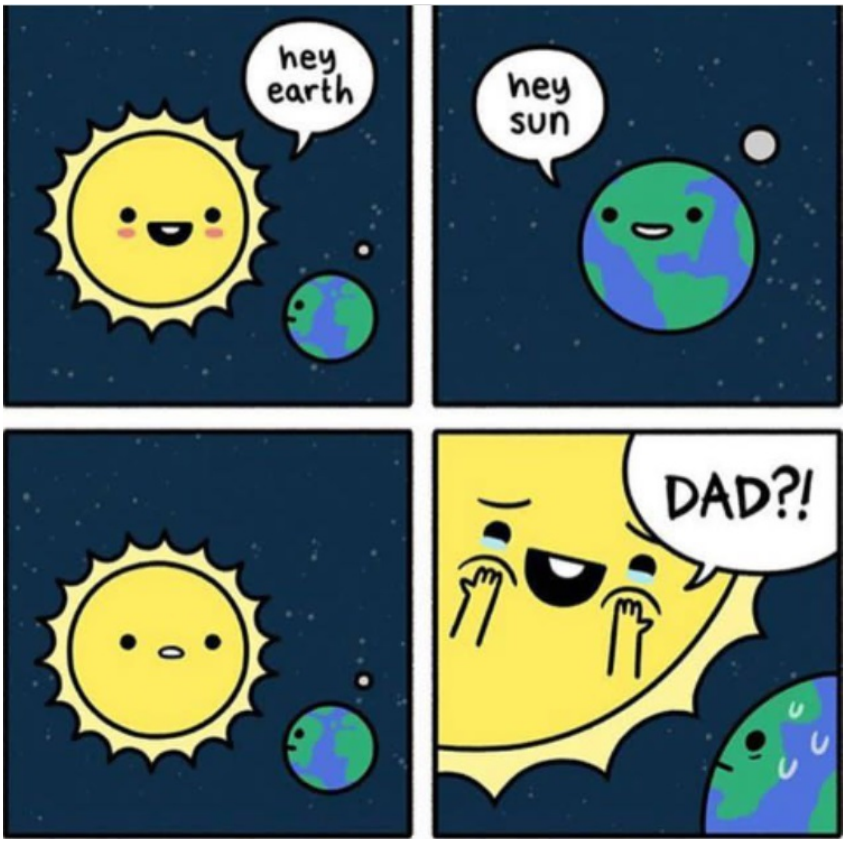
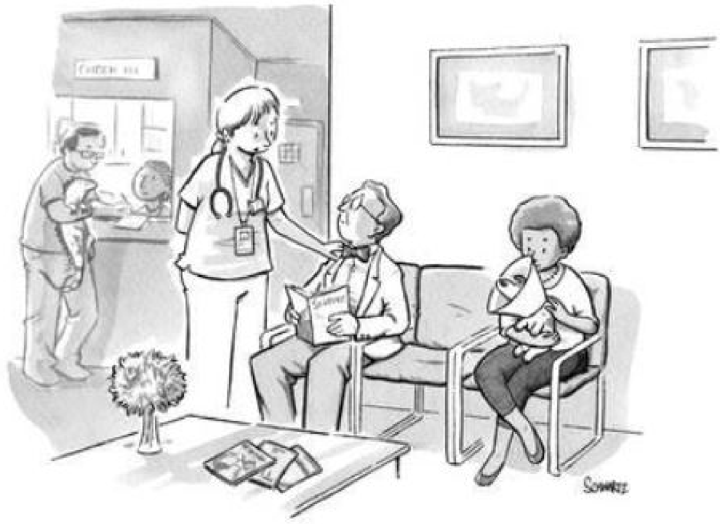
NEWTON'S LAWS OF CAT MOTION
1. A CAT IN MOTION TENDS TO STAY IN MOTION
ΣF=0 → dv/dt = 0.
v = Δx/Δt
2. A CAT AT REST TENDS TO STAY AT REST
rests natural state of cat.
F=ma
F_A=-F_B
3. WHENEVER A CAT EXERTS A FORCE UPON A SECOND CAT, THE SECOND CAT EXERTS AN EQUAL AND OPPOSITE FORCE UPON THE FIRST CAT.
4. THE ACCELERATION OF A CAT IS PROPORTIONAL TO THE FORCE ACTING UPON THE CAT.
kitty moves proportionally to the speed of the force acting upon it...
...which is, in this case, a laser pointer moving at the speed of light.
SCHRODINGER'S LAW OF CATS IN BOXES
A CAT IN A BOX MUST BE REGARDED AS EQUALLY IN AND OUT OF THE BOX
This law can be demonstrated through a simple experiment. Place a box on a flat surface. Wait. Check the box. It may or may not contain a cat, but it probably will.
FIRST LAW OF CAT THERMODYNAMICS
Heat and work are forms of energy transfer. Cats invariably conserve energy, through sitting next to heat sources and not working.
EXCEPTION TO GALILEAN PRINCIPLES OF MECHANICS
A cat occupies a privileged frame of reference.

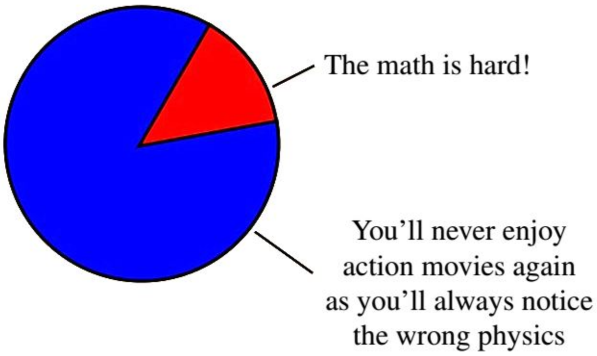


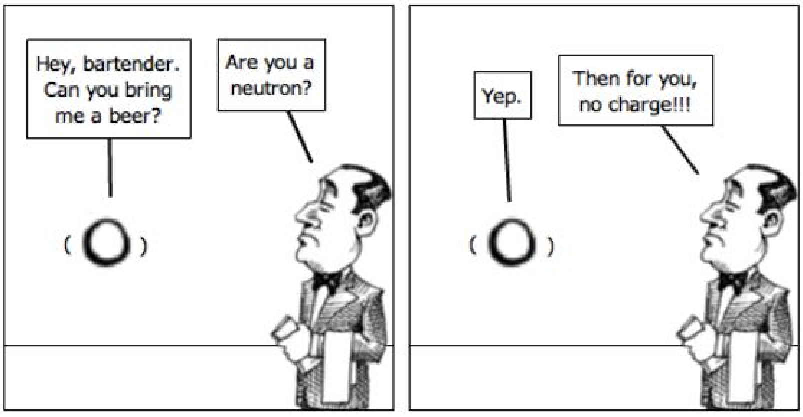
hey earth
hey sun
DAD?!



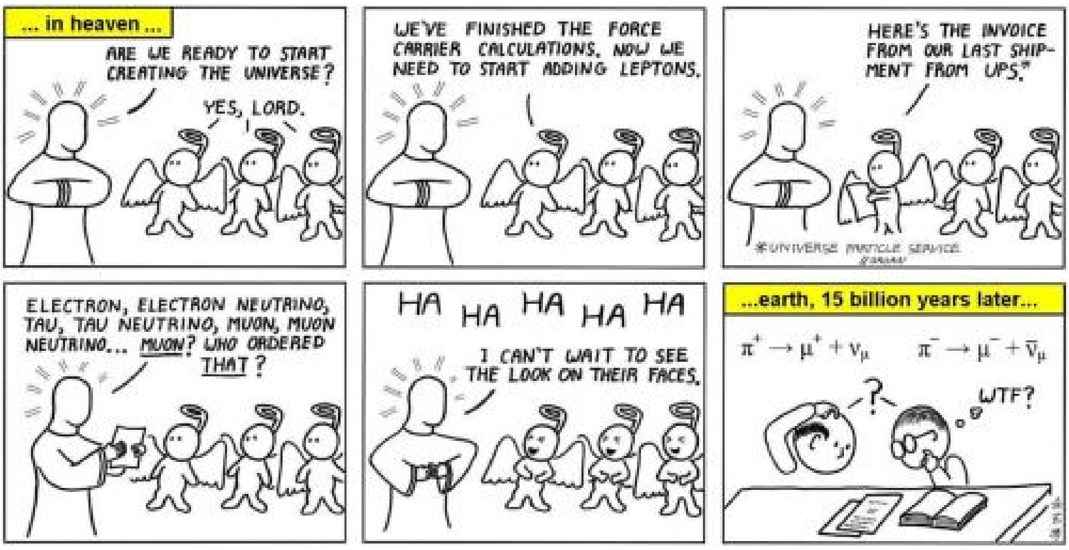
"About your cat, Mr. Schrödinger—I have good news and bad news."

Why is it a bad idea
to major in physics?





Hey, bartender. Can you bring me a beer?
Are you a neutron?
Yep.
Then for you, no charge!!!



... in heaven ...
ARE WE READY TO START CREATING THE UNIVERSE?
YES, LORD.
WE'VE FINISHED THE FORCE CARRIER CALCULATIONS. NOW WE NEED TO START ADDING LEPTONS.
HERE'S THE INVOICE FROM OUR LAST SHIPMENT FROM UPS.*

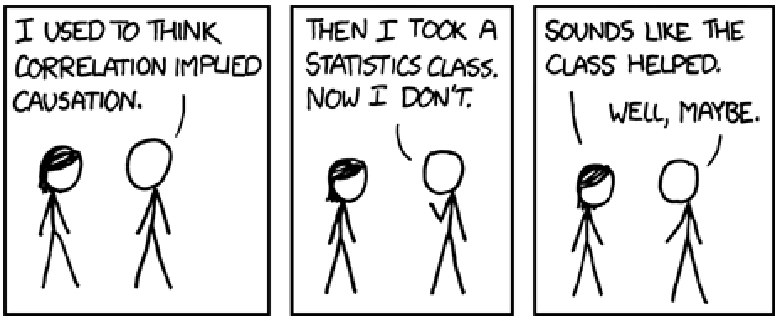
20.4. Statistics

Three statisticians go out for a static target shooting. The first statistician fired and shoots to the left, the second shot, but symmetrically on the right. The last does not shoot, but say triumphantly: "On average we got it!"



I USED TO THINK CORRELATION IMPLIED CAUSATION.
THEN I TOOK A STATISTICS CLASS. NOW I DON'T.
SOUNDS LIKE THE CLASS HELPED.
WELL, MAYBE.

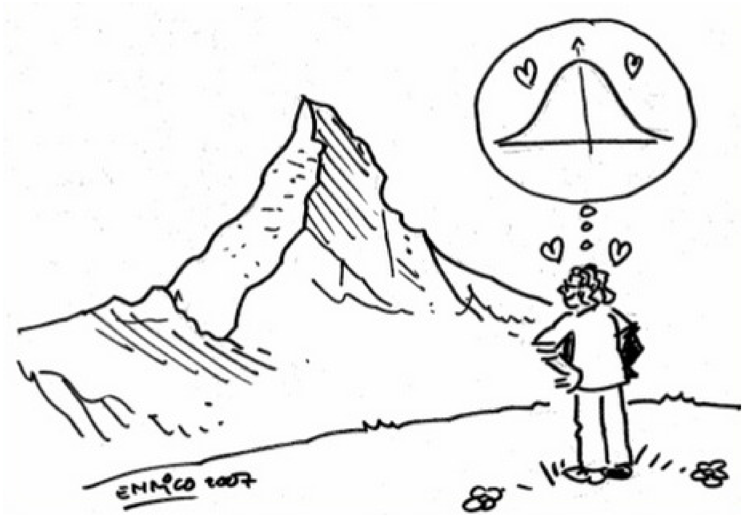
Figure 20.2: **source: www.xkcd.com (author: Randall Munroe)**

Patient: "Will I survive to this delicate operation?"

Surgeon: "Yes, I am absolutely sure that you will survive."

Patient: "How can you be so sure?"

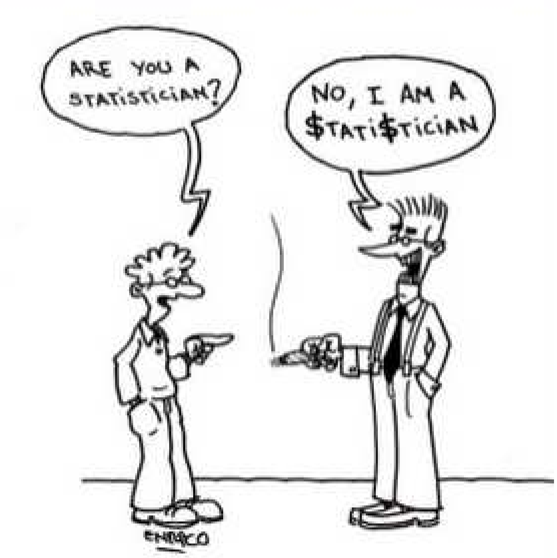
Surgeon: "9 out of 10 patients die during this operation and my ninth patient died yesterday."



ENRICO 2007

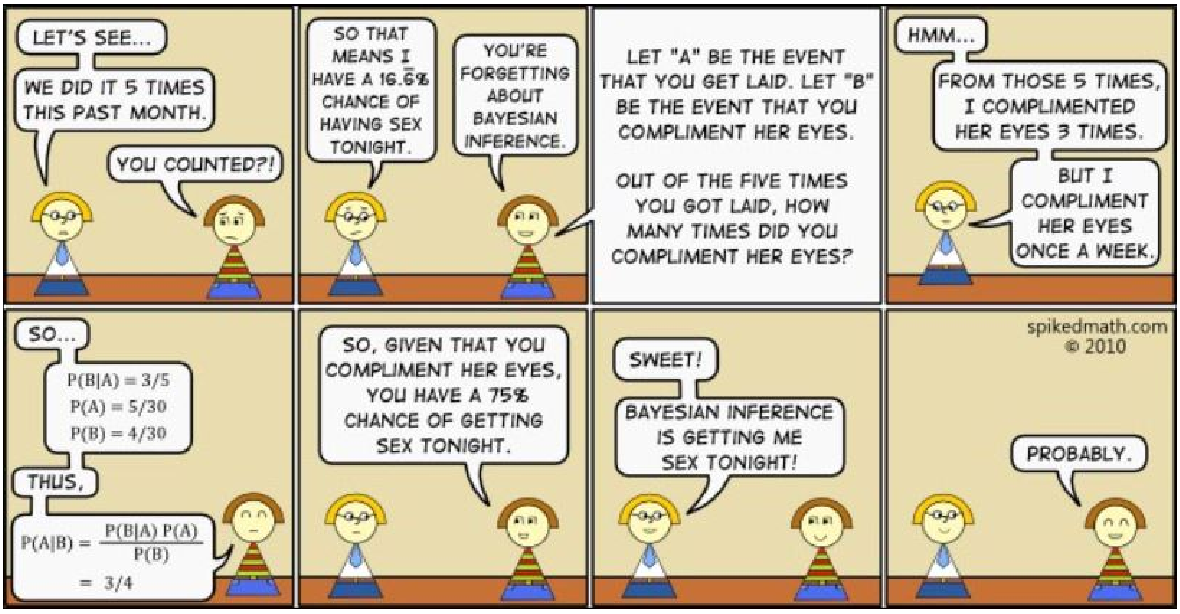
10 reasons to work in statistics field:

1. Estimate parameters is easier than fighting in real life
2. Statisticians are recognized people
3. You will learn the Greek alphabet entirely
4. The probability that you get a job in this area is > 0.9999
5. If you are fired, you can always convert yourself to engineering
6. You make this work in the confidence, with regularity and variability
7. You are normal and the rest of the world is wrong
8. The regression line seems better than the unemployment line
9. You never have to be exact - only approximate
10. Nobody understands what you do, then you are always right



A theist asks an atheist what is the most important value in life?

The atheist answers: the p-value.



LET'S SEE...
WE DID IT 5 TIMES THIS PAST MONTH.
YOU COUNTED?!
SO THAT MEANS I HAVE A $16.\overline{6}\%$ CHANCE OF HAVING SEX TONIGHT.
YOU'RE FORGETTING ABOUT BAYESIAN INFERENCE.
LET "A" BE THE EVENT THAT YOU GET LAID. LET "B" BE THE EVENT THAT YOU COMPLIMENT HER EYES.
OUT OF THE FIVE TIMES YOU GOT LAID, HOW MANY TIMES DID YOU COMPLIMENT HER EYES?
HMM...
FROM THOSE 5 TIMES, I COMPLIMENTED HER EYES 3 TIMES.
BUT I COMPLIMENT HER EYES ONCE A WEEK.
SO...
$P(B|A) = 3/5$
$P(A) = 5/30$
$P(B) = 4/30$
THUS,
$P(A|B) = \frac{P(B|A)\,P(A)}{P(B)} = 3/4$
SO, GIVEN THAT YOU COMPLIMENT HER EYES, YOU HAVE A 75% CHANCE OF GETTING SEX TONIGHT.
SWEET!
BAYESIAN INFERENCE IS GETTING ME SEX TONIGHT!

20.5. Chemistry

We've just discovered a new element:

- ELEMENT NUMBER: 115
- NAME: Woman
- SYMBOL: Wo
- ATOMIC MASS: Accepted as 60 kg; isotopes may vary from 40-200 kg.
- OCCURRENCE: Copious quantities in all urban areas
- PHYSICAL PROPERTIES:

  - Boils at room temperature

  - Freezes without any known reason

  - Melts if given special treatment

  - Bitter, if incorrectly used

  - Sweet as Honey if given a proper treatment.
- MOLECULAR STRUCTURE:

  Perfect? 90/60/90, growing int the U.S. with 60/90/120 and in the nordic countries as so-called "flat" 50/50/50
- CHEMICAL PROPERTIES:

  - Has great affinity for Gold, Silver and a range of precious stones.Absorbs in general great quantities of expensive substances.

  - May explode spontaneously without prior warning and for no known reason.

  - Insoluble in liquids but activity greatly increased by saturation in alcohol

  - Reactivity varies depending on the time of the day

  - Great ability to change mood and jealousy

  - Sensitive to certain constraints which sometimes transmit migraine
- COMMON USES:

  - Highly ornamental, especially in sports cars

  - Powerful cleaning agent

  - Can be great aid to relaxation.
- TEST:

  - Pure specimen turns rosy pink when happy

  - Turns green when placed behind a better specimen

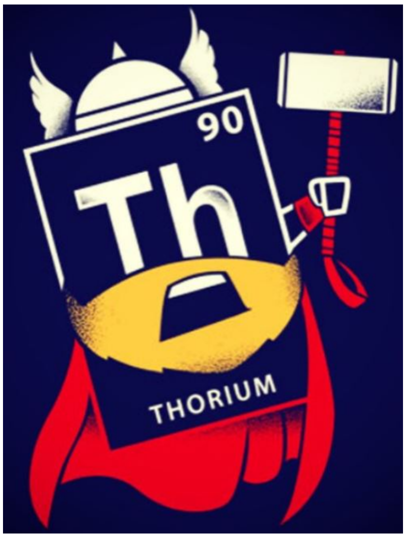
- PRECAUTIONS:

  - Highly dangerous if placed between the non-expert hands

  - Illegal to possess more than one, although several can be maintained at different locations as long as specimens do not come in direct contact with each other.

CAUTION:

Some South American researchers have discovered a way to produce them artificially, usually presented under the marks "transvestite" or "Drag-queen". Consume only the generic!



We’ve just discovered a new element:

- ELEMENT NUMBER: 116
- NAME: Man
- SYMBOL: Hm
- QUANTITATIVE ANALYSIS:

  Measured at 17 cm, although some isotopes exist in 25, 20, 13 and even 10 cm
- EXTRACTION LOCATION:

  Can be found in large quantities in the presence of a deposit of very pure Fm

- PHYSICAL PROPERTIES:

  - Surface covered with hair, steep in places, soft in others

  - Boil when it is shaken, will ice when placed in the presence of logic and common sense, liquefies when treated like a god

  - Becomes execrable when mixed with any alcohol

  - Can cause headaches (other body parts pains); handle with care

  - Decreases its entropy directly after its reaction with the element Fm (condition manifested by snoring ... zzzzz)

  - Its mass increases significantly with age, losing its reaction capacity

  - Dehydrates quickly in dry weather.

  - Rarely found in pure form after 14 years old

  - Often has an inexplicable attachment to its mother rock, making extraction difficult

  - If you put it under pressure it becomes too hard and unproductive; is productive only when used subtlety, with subterfuge and flattery

- CHEMICAL PROPERTIES:

  - Very strong tendency to react with the Fm element, although the reaction is sometimes endothermic

  - Deemed to be the best catalyst for the transformation reactions of the Fm element

  - Has the ability to react with almost anything

  - If the case of an important reaction the aspect of the element changes to dark red

  - If it is saturated with alcohol, it becomes inert and repulsive for most elements

  - Not suitable for household chores and cleaning operations

  - Not suitable either for family duties

  - Is neutral with respect to the courtesy and impartiality

- COMMON USES:

  - Transporting heavy things, driver, free dinners at the restaurant...

  - Possible use for sexual activity

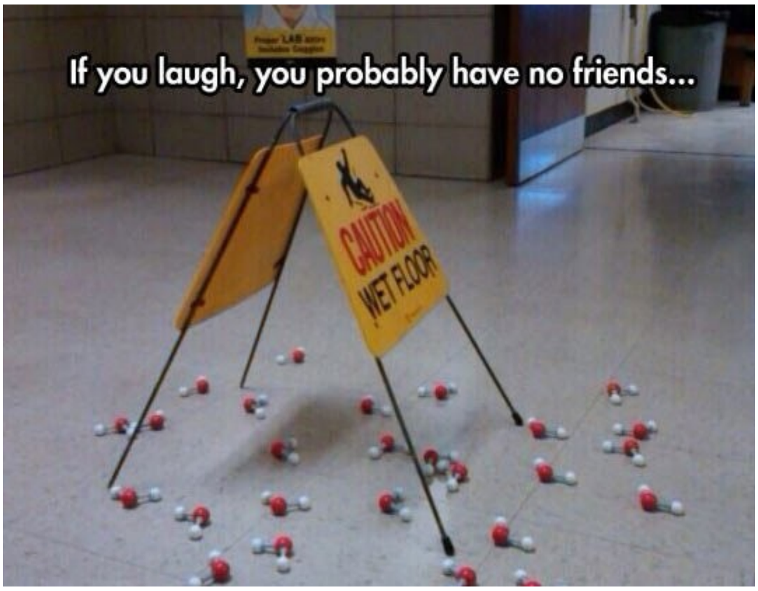
- TESTS:

  The purest specimens are not synonymous with purity, and those who have already served, are less pure

- HAZARDS:

  The reaction with another element Hm is extremely violent if the item Fm is the catalyst

---



The following is an actual question given on a University of Washington engineering mid term. The answer was so profound that the Professor shared it with colleagues, which is why we now have the pleasure of enjoying it as well.

Bonus Question: Is Hell exothermic (gives off heat) or Endothermic (absorbs heat)?

Most of the students wrote proofs of their beliefs using Boyle's Law, (gas cools off when it expands and heats up when it is compressed) or some variant. One student, however, wrote the following:

"First, we need to know how the mass of Hell is changing in time. So we need to know the rate that souls are moving into Hell and the rate they are leaving. I think that we can safely assume that once a soul gets to Hell, it will not leave. Therefore, no souls are leaving. As for how many souls are entering Hell, let's look at the different religions that exist in the world today. Some of these religions state that if you are not a member of their religion, you will go to Hell. Since there are more than one of these religions and since people do not belong to more than one religion, we can project that all souls go to Hell. With birth and death rates as they are, we can expect the number of souls in Hell to increase exponentially.

Now, we look at the rate of change of the volume in Hell because Boyle's Law states that in order for the temperature and pressure in Hell to stay the same, the volume of Hell has to expand as souls are added. This gives two possibilities:

1. If Hell is expanding at a slower rate than the rate at which souls enter Hell, then the temperature and pressure in Hell will increase until all Hell breaks loose.
2. Of course, if Hell is expanding at a rate faster than the increase of souls in Hell, then the temperature and pressure will drop until Hell freezes over.

So which is it? If we accept the postulate given to me by Teresa Banyan during my Freshman year, "...that it will be a cold day in Hell before I sleep with you." and take into account the fact that I still have not succeeded in having sexual relations with her, then, #2 cannot be true, and thus I am sure that Hell is exothermic and will not freeze."

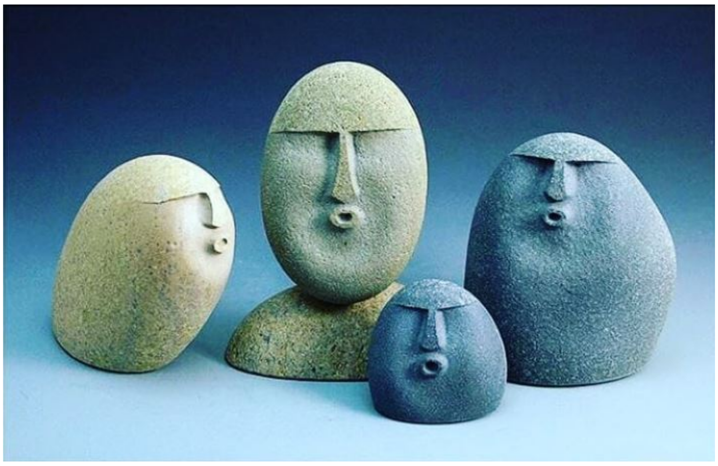
This student received the only A.

A chemist walks into a pharmacy and asks the pharmacist: "Do you have any acetylsalicylic acid?"

- "You mean aspirin?" asked the pharmacist.
- "That's it, I can never remember that word."

Teacher asks: what's the element symbol of Oxygen.

Students:



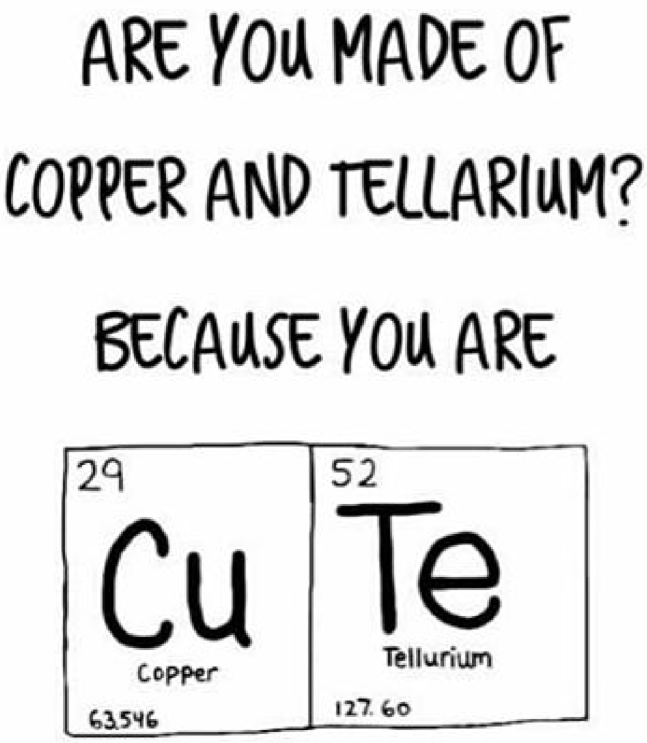
A physicist, biologist and a chemist were going to the ocean for the first time.

- The physicist saw the ocean and was fascinated by the waves. He said he wanted to do some research on the fluid dynamics of the waves and walked into the ocean. Obviously he was drowned and never returned.
- The biologist said he wanted to do research on the flora and fauna inside the ocean and walked inside the ocean. He too, never returned.

- The chemist waited for a long time and afterwards, wrote the observation: "The physicist and the biologist are soluble in ocean water".

CLASSIFICATION OF CHEMISTRY

- *Physical Chemistry*: The pitiful attempt to apply $y = mx + b$ to everything in the universe.
- *Organic Chemistry*: The practice of transmuting vile substances into publications.
- *Inorganic Chemistry*: That which is left over after the organic, analytical, and physical chemists get through picking over the periodic table.
- *Chemical Engineering*: The practice of doing for a profit what an organic chemist only does for fun.



ARE YOU MADE OF

épistétou.
fb.me/EBBHenglish/ fb.me/RoMEBBH
Welcome to our SAY-MY-NAME Quiz on Science! Ready?
Yeah, SCIENCE!!!
Ok, let's go: I am sometimes called 1,3,7-trimethylxanthine or Methyltheobromine and I am a member of the methylxanthines family. I can cause paralysis or death in some insects. In humans, I am known to cause overstimulation of the central nervous system and symptoms like anxiety, involontary contractions, polyuria, gastrointestinal disorders, cardiac arythmy or tachycardia. SAY MY NAME.
Err... Some... Well, some CHEMICAL SHIT, I guess.
CAFFEINE! Next one: Na+ and Cl- ions bonded in a crystal structure, I am used in the production of caustic soda, hydrochloric acid and chlorine gas through different electrolytic processes. I am also probably guilty of almost 2 millions deaths every year. SAY MY NAME.
Obviously, this time, CHEMICAL SHIT, Yo!
No. SALT. C'mon! The last one is easy: my chemical formula is CH3-CH2-OH, I'm VERY poisonous, volatile and flammable. I'm a known carcinogenic and responsible for many, many deaths worlwilde every year. However heavily used by the food industry. NOW, SAY MY NAME.
CAN'T BE anything else than CHEMICAL SHIT.
ETHYL ALCOHOL!
But... All these words! It sounds SO CHEMICAL!
You're Goddamn Right.
Then it MUST be DANGEROUS!
No. I AM THE DANGER, Jesse.
RôM.
@Evidencebbh

20.6. Engineering

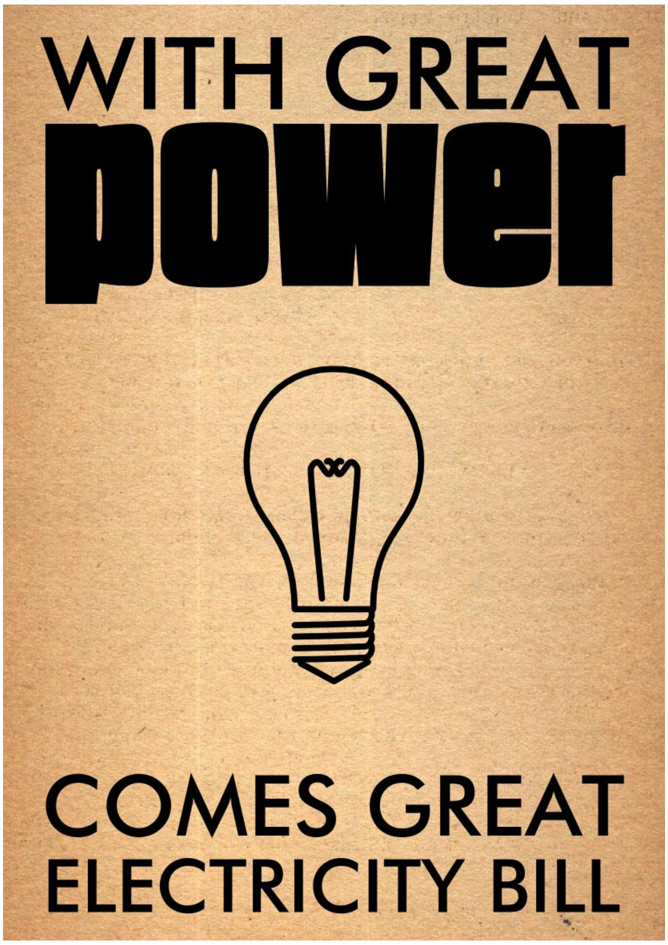
Scientists at NASA built a device to launch dead chickens at the wind-shields of airliners, military jets, the space shuttle, etc. The idea being to simulate collisions with airborne fowl to test the strength of the wind-shields.

British engineers heard about the device and were eager to test it on the wind-shields of their new high speed trains. Arrangements were made and a device was sent to the British engineers.

When device was fired, the British engineers were shocked... the chicken hurled out of the barrel, crashed into the shatterproof shield, smashed it to smithereens, blasted through the control console, snapped the engineer's back-rest in two and embedded itself in the back wall of the cabin.

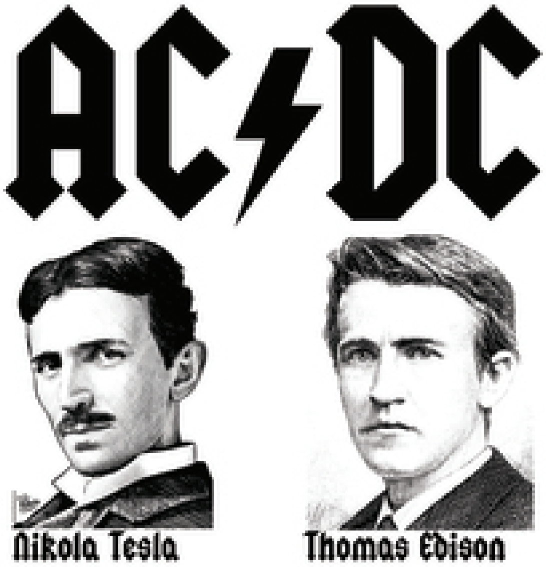
The horrified Brits sent NASA the disastrous results of the experiment, along with the designs of the wind-shield and begged the US scientists for suggestions.

NASA responded with a one-line memo: "Defrost the chicken."



Deux ingénieurs et un ami non-ingénieurs se rencontrent à un bar un vendredi soir pour raconter leur semaine de travail.

- Le premier ingénieur: "J'ai passé une semaine horrible à faire des plans un à la fois chaque jour."
- Le deuxième ingénieur: "J'ai fait un peu moins pire. J'ai au moins pu faire des plans complets plusieurs fois par jour."
- Le troisième ami non-ingénieur: "Ben les gars vous en avez de la chance! Moi je me limite à des plans culs qu'une fois par mois".



Trying to understand engineers:

- Trial N°1

  An engineer tell to a friend:"Well, yesterday I was walking home, minding my own business, when a beautiful woman rode up to me on this bike. She threw the bike to the ground, took off all her clothes and said, 'Take what you want!'"

  The friend (also engineer) approvingly, "Good choice. The clothes probably wouldn't have fit."

- Trial N°2

  For an optimist, the glass is half full. For a pessimistic person, it is half empty. To the engineer, it is twice as large as needed.

- Trial N°3

  A pastor, a doctor and an engineer were waiting one morning for a particularly slow group of golfers. After a moment the engineer cry: "What's with these guys? We must have been waiting for 15 minutes!". The doctor also desperate says: " I don't know, but I've never seen such ineptitude!". The pastor the says: "Hey, here comes the greens keeper. Let's have a word with him. [dramatic pause] Hi George. Say, what's with that group ahead of us? They're rather slow, aren't they?". The greens keeper answers: " Oh, yes, that's a group of blind fire fighters. They lost their sight saving our clubhouse from a fire last year, so we always let them play for free anytime.". The group is silent for a moment... The pastor then says: "That's so sad. I think I will say a special prayer for them tonight.". And the doctor:" Good idea. And I'm going to contact my ophthalmologist buddy and see if there's anything he can do for them.". Finally the engineer says " Why the fuck can't these guys play at night?".

- Trial N°4

  A engineer was crossing a road one day when a frog called out to him and said, "If you kiss me, I'll turn into a beautiful princess." He bent over, picked up the frog, and put it in his pocket. The frog spoke up again and said, "If you kiss me and turn me back into a beautiful princess, I will tell everyone how smart and brave you are and how you are my hero" The man took the frog out of his pocket, smiled at it, and returned it to his pocket. The frog spoke up again and said, "If you kiss me and turn me back into a beautiful princess, I will be your loving companion for an entire week." The man took the frog out of his pocket, smiled at it, and returned it to his pocket. The frog then cried out, "If you kiss me and turn me back into a princess, I'll stay with you for a year and do ANYTHING you want." Again the man took the frog out, smiled at it, and put it back into his pocket. Finally, the frog asked, "What is the matter? I've told you I'm a beautiful princess, that I'll stay with you for a year and do anything you want. Why won't you kiss me?". The man said, "Look, I'm an engineer. I don't have time for a girlfriend, but a talking frog is cool.".

- Trial N°5

  A reporter interviews a Corsican farmer: "Tell me, how do you draw the roads here in your country?". The farmer replies, "beh, we launch a donkey and look where it goes into the mountains .... and that's where we passed the road". The journalist then retorts: "and if you do not have a donkey?". The farmer replies: "ah beh... we take an engineer...".

VIA 9GAG.COM

During the heat of the space race in the 11960s (holocene calendar), NASA decided it needed a ball point pen to write in the zero gravity confines of its space capsules.

After considerable research and development, the Astronaut Pen was developed at a cost of $1 million U.S. The pen worked and also enjoyed some modest success as a novelty item back here on Earth.

The Soviet Union, faced with the same problem, used a pencil.

The great mathematician John Von Neumann was consulted by a group who was building a rocket ship to send into outer space. When he saw the incomplete structure, he asked, "Where did you get the plans for this ship?"

He was told, "We have our own staff of engineers."

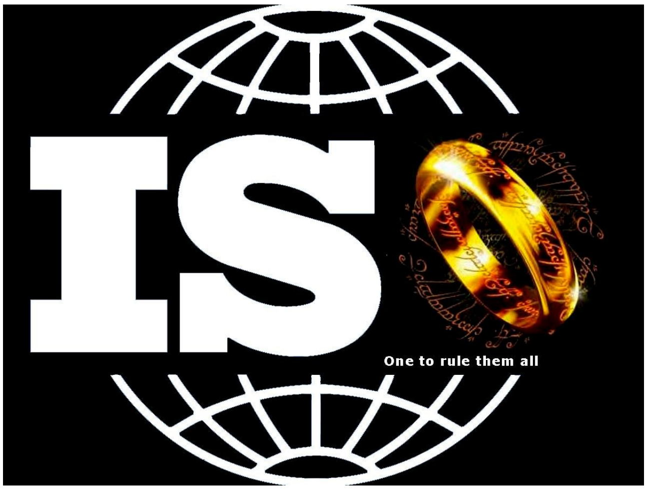
He disdainfully replied (using the Gregorian calendar): "Engineers! Why, I have complete sewn up the whole mathematical theory of rocketry. See my paper of 1952."

Well, the group consulted the 1952 paper, completely scrapped their $10 million structure, and rebuilt the rocket exactly according to Von Neumann's plans. The minute they launched it, the entire structure blew up. They angrily called Von Neumann back and said: "We followed your instructions to the letter. Yet when we started it, it blew up! Why?"

Von Neumann replied (still using the Gregorian calendar), "Ah, yes! That is technically known as the blow-up problem - I treated that in my paper of 1954."

In an electronic laboratory:

- Say, what’s the trailer in the parking?
- The trailer?
- Yeah, the driver says you’re aware ...
- Oh yes !! I ordered a 1 Farad capacitor .



IS
One to rule them all

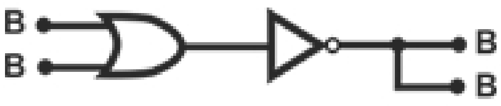
What engineers say and what they mean by it:

- Major Technological Breakthrough: Back to the drawing board.
- Developed after years of intensive research: It was discovered by accident.
- The designs are well within allowable limits: We just made it, stretching a point or two.

- Test results were extremely gratifying: It works, and are we surprised!
- Customer satisfaction is believed assured: We are so far behind schedule that the customer was happy to get anything at all.
- Close project coordination: We should have asked someone else.
- Project slightly behind original schedule due to unforeseen difficulties: We are working on something else.
- The design will be finalized in the next reporting period: We haven't started this job yet, but we've got to say something.
- A number of different approaches are being tried: We don't know where we're going, but we're moving.
- Extensive effort is being applied on a fresh approach to the problem: We just hired three new guys; we'll let them kick it around for a while.
- Preliminary operational tests are inconclusive: The darn thing blew up when we threw the switch.
- The entire concept will have to be abandoned: The only guy who understood the thing quit.
- Modifications are underway to correct certain minor difficulties: We threw the whole thing out and are starting from scratch.
- Essentially complete: Half done.
- We predict...: We hope to God!
- Drawing release is lagging: Not a single drawing exists.
- Risk is high, but acceptable: 100 to 1 odds, or with 10 times the budget and 10 times the manpower, we may have a 50/50 chance.
- Serious, but not insurmountable, problems: It will take a miracle. God should be the program manager.
- Not well defined: Nobody has thought about it.
- Requires further analysis and management attention: Totally out of control.
- The project is designed for high availability: Malfunctions will be blamed on the operators mistakes.
- This project has low maintenance requirements: We wouldn't let the technicians change a light bulb, much less fool around with our baby.
- The software is being developed without excessive process overhead: The documentation will be written in clear and lucid Chinese.

- The delivery is scheduled for the last quarter of next year: This leaves us plenty of time to decide who to blame for it being late.

- How many first year engineering students does it take to change a light bulb?: None. That's a second year subject.
- How many second year engineering students does it take to change a light bulb?: One, but the rest of the class copies the report
- How many third year engineering students does it take to change a light bulb?: Will this question be in the final examination?
- How many civil engineers does it take to change a light bulb?: Two. One to do it and one to steady the chandelier
- How many electrical engineers does it take to change a light bulb?: None. They simply redefine darkness as the industry standard
- How many computer engineers does it take to change a light bulb?: Why bother? The socket will be obsolete in six months anyway
- How many mechanical engineers does it take to change a light bulb?: Five. One to decide which way the bulb ought to turn, one to calculate the force required, one to design a tool with which to turn the bulb, one to design a comfortable - but functional - hand grip, and one to use all this equipment.
- How many nuclear engineers does it take to change a light bulb?: Seven. One to install the new bulb and six to figure out what to do with the old one for the next 10,000 years.



2B OR NOT 2B

This happens in Moscow: a couple of tourists ask for it's way, on a bridge to a Russian engineer.

The guy answer: "You are going through, and within 50 meters, turn right..."

Thanks from the tourists... And they leave. So the guy runs behind them:

"Wait, wait! I just remembered that the bridge is 70 meters. If you turn right after 50 meters, as I have told you, you will fall into the water".

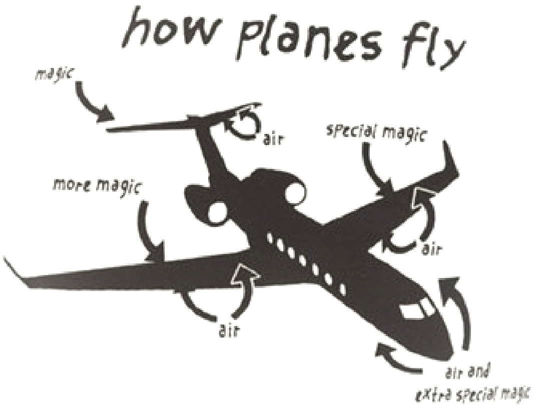
A quality engineers team is working on the FMECA for a new chemical factory. After several weeks, during the debriefing meeting:

Quality engineers: "Our conclusion is: there's a 1/10,000 rate for the plant to blow up, killing many people and inducing terrible ecological crisis, it's ethically unacceptable !"

Boss: "Standards are talking about an acceptable risk for a 1/7,000 rate"

The team regroups and talk, then:

Quality engineers: "Our conclusion is: You have an over-quality problem, it's ethically unacceptable!"



A guy was seated next to a 10-year-old girl on an airplane. Being bored, he turned to the girl and said, "Let's talk. I've heard that flights go quicker if you strike up a conversation with your fellow passenger."

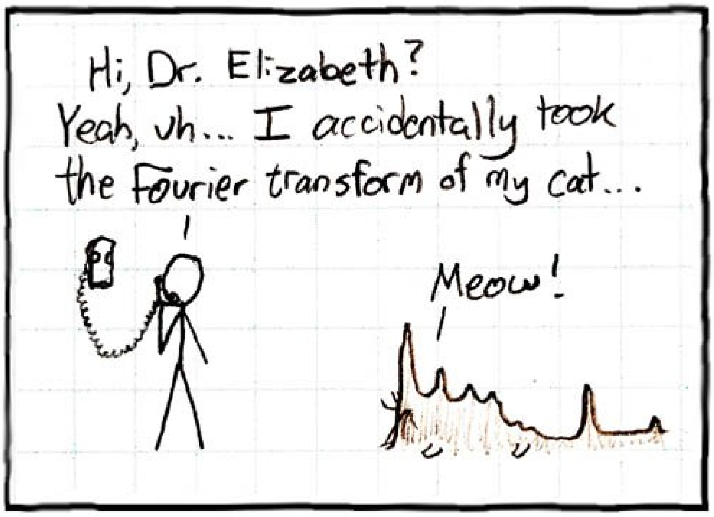
The girl, who was reading a book, closed it slowly and said to the guy, "What would you like to talk about?"

"Oh, I don't know" said the guy. "How about nuclear physics?"

"OK" she said. "That could be an interesting topic. But let me ask you a question first. A horse, a cow and a deer all eat the same stuff... grass. Yet a deer excretes little pellets, while a cow turns out a flat patty, and a horse produces clumps of dried grass. Why do you suppose that is?"

The guy thought about it and said, "Hmmm, I have no idea."

To which the girl replied, "Do you really feel qualified to discuss nuclear power when you don't know shit?".



Hi, Dr. Elizabeth?
Yeah, uh... I accidentally took the Fourier transform of my cat...
Meow!

Newton asked: How write 4 in between 5?

1. Medicine students said: Joke!
2. Science students said: Impossible!
3. Management students said: Not found on the internet!
4. Engineering student said: "F(IV)E"

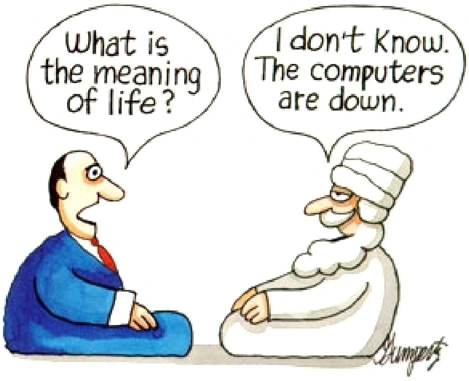
20.7. Computing



What is the meaning of life?
I don't know. The computers are down.

If you want to be a hacker, you will have to use Linux.

Here are 2 solutions :

1. You are a capitalistic bourgeois and you buy it at Fry's for $150.
2. You are an asshole, and then you download it on the net.

Of course you belong to the second category, so you have to use your FTP client and wait a few hours while your are downloading a Slack or a Debian. Try not to use Mandriva, this is for the public. You must not forget that you are an uNdERgrOuNd guy now, it's normal, you're a Hacker.

O.K., now you have got Linux, you can forget it. You do not need to lose your time learning how this new Operating System works and that you will never use because Xwing vs Tie Fighter doesn't run on it. The best way is to delete lilo, like that you will be sure to boot on Windows Vista. This elegant solution is practised by many guys like you. The easiest way is to invoke disk /mbr in a DOS session, it will delete lilo which was installed on your hard drive's MBR. Good, you do not need to care about Linux anymore.

The goal is to have it, not to know how using it.

Okay, but then how can I show to everybody that I have Linux and that I am a rebel ?".

That is a natural issue. Hopefully, I thought about you little looser, here comes sentences that you have to tell everybody about Linux:

- "Linux is really powerful, you are free to do what ever you want with it compare to these fascists systems like Winblows. Anyway, M$ is to crappy."

- "Well, if you are a beginner, you better not use Linux, this thing is for eLiteS. You, you are better using WinFuck."
- "Hey ! Where could I find the libc5.4.36 ? Because the 5.4.35 is not compatible with the modifications have done on my kernel."
- "Netscape sucks, it creates core dumps over 50 mo when it launches !I prefer using Lynx, text mode is much easier."
- "Wooooww what a fool ! He installed a Mandriva !! Only Debian is good, at least you know that you are the master of your system. No really, Mandriva is really to crappy."

With these sentences, you will quickly belong to the "okay, he's an asshole, but an asshole using Linux" category, this is the first step to become a real hacker. Now everybody knows you have Linux, you must move to the next stage, become the guy who knows everything about networks, who masters ICMP like a god. This is the second step of your long journey.

Now, you have to put your hands on the money. Go to Fry's and buy any books about Unix and networks. The main thing is a complicated title. A "rlogin protocol on ethernet sub-address" would have the best effect. Buy them even if you do not understand the titles, you just need to have impressive books : You are not suppose to read them, it is just to impress your friends, whom are assholes just like you.

The best way is to buy a book like "TCP/IP Volume 43" and learn by heart random words: socket, sub-address, FDDI, telnet, for example. Then you will use them in your sentences, even out of context, nobody will check what you are saying. For example, for feel to swing sentences like : "How many packets over FDDI networks does a telnet transmits ?". God, I swear it on a good cowboy channel, that will always impress and nobody will tell you that what you have just said has no meaning. Don't worry.

Then, put these books in your bedroom, the most complicated titles in the most visible areas. Damage a few pages' corners to make it credible. Take some paper and draw network diagrams, or add things like 123.44.5.34 root / lydia to make others believe you spend your days cracking passwords like a mad. Do not hesitated scanning Mitnick's photos and hang them above your bed, or put stickers of skulls on your computer to show that now, you are a thug, a dangerous guy. To complete your new identity and truly become a hacker, you mustn't hesitate to say great things like : "I am thirsty for knowledge". Okay, you are in high school since 10 ten years, but it does not matter, you love learning anyway, hacking is a passion and you have a lot of willpower. Specify that you never do any damages to all the computers you hack into. Say you are doing that for "Intellectual Challenge". Yes, this time, you will have to force yourself not to laugh hard, so train yourself in front of the mirror before.

When people are dangerous like you, they must meet with other crooks in order to jeopardize the State's security. For this, there is THE thugs' rendez-vous, called the "Meet 2600". Every month, you will go to a MacDo in Paris, place of Italy, and there you will meet very important guys, who rebooted the entire Internet with a Visual Basic program and have special hair cuts like rebels of the society.

Okay, you will not learn much in this meetings, losers who go over there masturbate each other thinking "Yeah, we are hAcKeRz, we are ruthless, real men. Oh shit, it is already 6 pm, I have to go home otherwise my mum will kill me." But you will still feel real thrill thinking that the MacDo is full of cameras and microphones, and that the employees are agents from the DST who are listening to dangerous conversations such as :

- Asshole 1: How much is the Whooper ?
- Asshole 2: Uh, MacDo does Whoopers now ?
- Asshole 1: I thought they always did, no

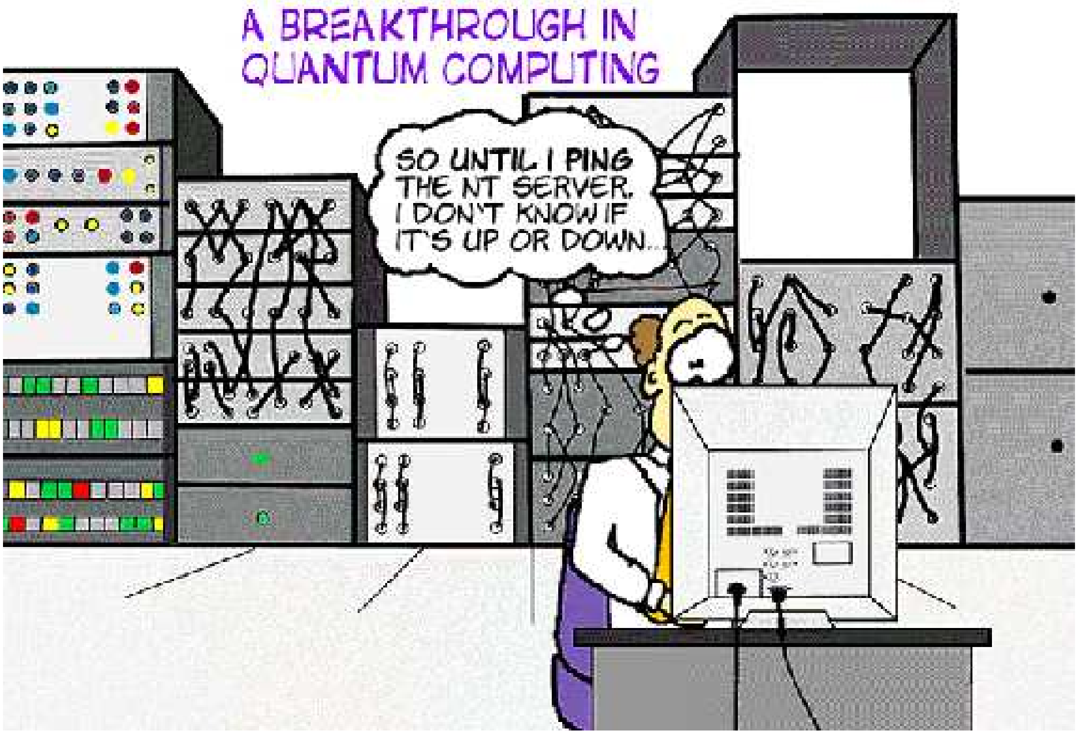
The hAcKeRz' community also goes to raves. It is a part of the message "rebel no future fuck da society, we take ecstasy and listen to rubbish but we don't care, it is great because it is prohibited". Feel free to go in these places, it's a part of the lost culture to go in these hot parties.

You, you are a real hacker and you hear well to spread your knowledge in order to educate others like you. For this reason, there is e-zines. They include the best known as NoWay or NoRoute where the worse alongside the best (which is unfortunate for the best . . .) but there is also big shits who deserve to be more famous like the excellent Core-Dump who talks in an English that even my cat understands better than me.

Obviously, you have never read any books about Unix, you never hacked a machine in your life so you do not know what to write. Don't worry, you are not the only one to be in such a situation. The best thing to do is to write a rap article talking about your last rave or plunder anarchist magazines without understanding what you are talking about. If you decide plunder Phrack, do not hesitate to correct the guy or add more complicated stuff, nobody will check. Come on, free yourself, you are thirsty for knowledge, do not forget.

Now, for sure, you have truly become a hacker, a IRC rabble, an Internet thug, you are scaring government agencies and IBM wants to hire you to secure their network because this stupid Henry created a new Internet virus. So, you will have to, on daily basis, behave like a hacker, a real, a true, which means having a hacker's spirit and talking like a hacker.

A hacker primarily lives on IRC. Once your friends and your family will notice that you have changed, that you are not the same man anymore, you will have to spread the news on IRC in order to make new friends whom are assholes like you. Say goodbye to either #flours nor #friendship, now you will go down to the bottom of the IRC, the cyber-bronx, nuke-city, where only the real bruisers can be respected in this world of violence. To succeed, you will have to go from the asshole hacker status to an asshole on IRC who pretends being Mitnick, I mean a c0wb0y.



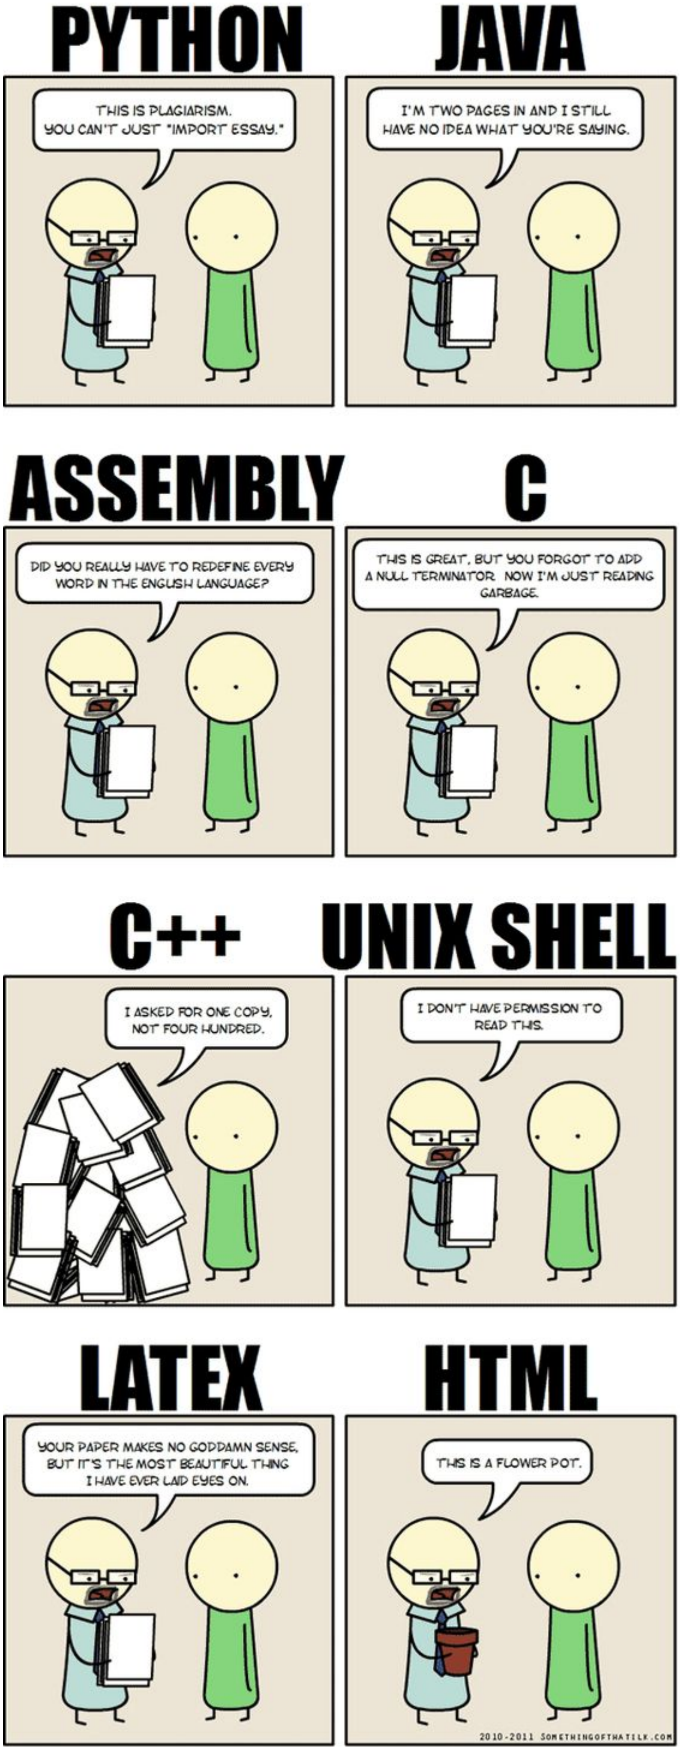
A BREAKTHROUGH IN QUANTUM COMPUTING
SO UNTIL I PING THE NT SERVER, I DON'T KNOW IF IT'S UP OR DOWN...

The Top 20 replies by programmers when their programs do not work:

20. "That's weird..."
19. "It's never done that before."
18. "It worked yesterday."
17. "How is that possible?"
16. "It must be a hardware problem."
15. "What did you type in wrong to get it to crash?"
14. "There is something funky in your data."
13. "I haven't touched that module in weeks!"
12. "You must have the wrong version."
11. "It's just some unlucky coincidence."
10. "I can't test everything!"
9. "THIS can't be the source of THAT."
8. "It works, but it hasn't been tested."
7. "Somebody must have changed my code."
6. "Did you check for a virus on your system?"
5. "Even though it doesn't work, how does it feel?
4. "You can't use that version on your system."
3. "Why do you want to do it that way?"
2. "Where were you when the program blew up?"

And the Number One reply by programmers when their programs don't work:

1. "It works on my machine."



PYTHON
THIS IS PLAGIARISM. YOU CAN'T JUST "IMPORT ESSAY."
JAVA
I'M TWO PAGES IN AND I STILL HAVE NO IDEA WHAT YOU'RE SAYING.
ASSEMBLY
DID YOU REALLY HAVE TO REDEFINE EVERY WORD IN THE ENGLISH LANGUAGE?
C
THIS IS GREAT, BUT YOU FORGOT TO ADD A NULL TERMINATOR. NOW I'M JUST READING GARBAGE.
C++
I ASKED FOR ONE COPY, NOT FOUR HUNDRED.
UNIX SHELL
I DON'T HAVE PERMISSION TO READ THIS.
LATEX
YOUR PAPER MAKES NO GODDAMN SENSE, BUT IT'S THE MOST BEAUTIFUL THING I HAVE EVER LAID EYES ON.
HTML
THIS IS A FLOWER POT.
2010-2011 SOMETHINGOFTHATILK.COM

How the way people code "Hello World" varies depending on their age and job:

- High School/Jr. High

```
10 PRINT "HELLO WORLD"
20 END
```

- First year in College

```
program Hello(input, output)
begin
writeln('Hello World')
end.
```

- Senior year in College

```
(defun hello
(print
(cons 'Hello (list 'World))))
```

- New professional

```
#include <stdio.h>
void main(void)
{
char *message[] = {"Hello ", "World"};
int i;
for(i = 0; i < 2; ++i)
printf("%s", message[i]);
printf("
n");
}
```

- Seasoned professional

```
#include <iostream.h>
#include <string.h>
class string{
private:
int size;
char *ptr;
public:
string() : size(0), ptr(new char('\0')) {}
string(const string &s) : size(s.size)
{
ptr = new char[size + 1];
strcpy(ptr, s.ptr);
}
string()
{
delete [] ptr;
}
friend ostream & operator «(ostream & , const string & );
string & operator=(const char *);
};
ostream & operator«(ostream & stream, const string & s)
{
return(stream « s.ptr);
}
string &string::operator=(const char *chrs)
{
if (this != & chrs)
{
delete [] ptr;
size = strlen(chrs);
ptr = new char[size + 1];
strcpy(ptr, chrs);
}
return(*this);
}
int main()
{
string str;
str = "Hello World";
cout « str « endl;
return(0); }
```

- System Administrator

```
#include <stdio.h>
#include <stdlib.h>
main()
{
char *tmp;
int i=0;
tmp=(char *)malloc(1024*sizeof(char));
while (tmp[i]="Hello Wolrd"[i++]);
i=(int)tmp[8];
tmp[8]=tmp[9];
tmp[9]=(char)i;
printf("%s \n",tmp);
}
```

- Apprentice Hacker

```
#!/usr/local/bin/perl
$msg="Hello, world.\n";
if ($#ARGV >= 0) { while(defined($arg=shift(@ARGV))) {
$outfilename = $arg;
open(FILE, ">" . $outfilename) || die "Can't write $arg: $! \n";
print (FILE $msg);
close(FILE) || die "Can't close $arg:  $!\n";
} } else {
print ($msg);
}
1;
```

- Experienced Hacker

```
#include <stdio.h>
#include <string.h>
#define S "Hello, World
n"
main(){exit(printf(S) == strlen(S) ? 0 :  1);}
```

- Seasoned Hacker

```
%cc -o a.out  /src/misc/hw/hw.c
%a.out
Hello, world.
Guru Hacker
%cat Hello, world.
```

- New Manager (do you remember?)

```
10 PRINT "HELLO WORLD"
20 END
```

- Middle Manager

```
mail -s "Hello, world." bob@b12
Bob, could you please write me a program that prints "Hello,
world."?
I need it by tomorrow.
D̂
```

- Senior Manager

```
%zmail jim
I need a "Hello, world." program by this afternoon.
```

- Chief Executive

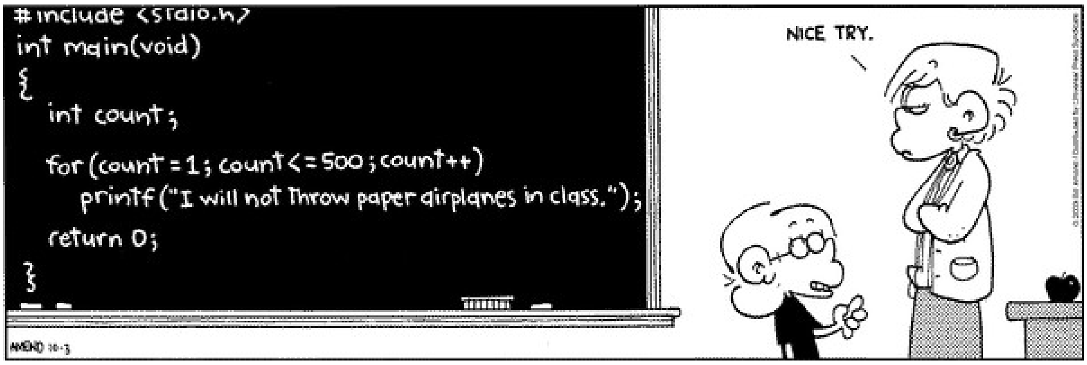
```
%letter
letter:  Command not found.  %mail
To:  X̂ F̂ Ĉ
%help mail
help:  Command not found.
%damn!
!:Event unrecognized
% logout
```

- Research Scientist

```
PROGRAM HELLO
PRINT *, 'Hello World'
END
```

- Older research Scientist

```
WRITE (6, 100)
100 FORMAT (1H ,11HHELLO WORLD)
CALL EXIT
END
```

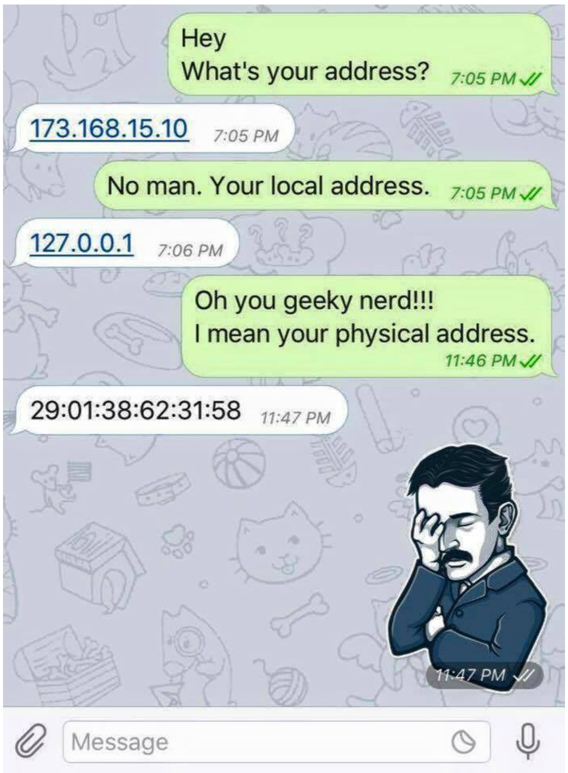


```
#include <stdio.h>
int main(void)
{
  int count;
  for(count=1;count<=500;count++)
     printf("I will not Throw paper airplanes in class.");
  return 0;
}
```

What the software engineers says... and what must be understood:

- We will put this project on schedule: We will take care of it if we have nothing else to do
- This is a completely new program!: It's absolutely not compatible with the old version
- This program requires no maintenance: It is impossible to debug
- This program requires little maintenance: It's almost impossible to debug
- We will respect the standards: It has always been like that and it's not going to change now that
- We want to respect the standards: You're not going to control everything that we do
- The new version of this program is 100% compatible with the previous: We did not touch anything
- Different approaches have been tried: We still trying to guess what happens.
- We approach a solution: We met for coffee...
- The preliminary tests were not satisfying: This damn program crashed as soon as we launch it

- We'll have to abandon the entire concept: The only person who understood something just resigned
- We prepare a comprehensive report, according to an entirely new approach: We just hired three newbie who left school
- This is a major breakthrough: We still can not understand why it does not work
- This is the result of years of development: We were finally able to operate a piece of the program ...
- We are working on it: We are so in trouble that it's hopeless
- Tell us what you think: We will listen to what you have to say as it does not undermine what is already done, or what we have decided to
- We'll take a look: Forget it! We have enough problems like that ...
- I have not received your e-mail: It's been ages that I have not checked my email...



Hey
What's your address? 7:05 PM

173.168.15.10 7:05 PM

No man. Your local address. 7:05 PM

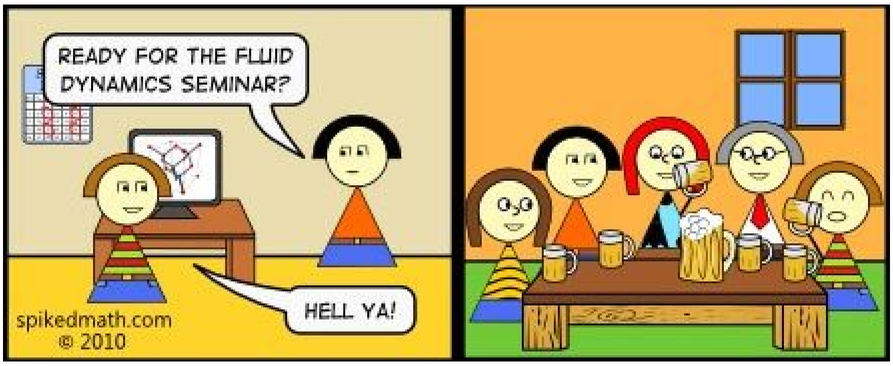
20.8. Social Sciences

To understand the marketing vocabulary..... and avoid appearing ridiculous in an evening party with colleagues:

1. Michael is at a party and sees a very attractive girl. He approaches her and says: "I am a very good shot". This is named the "direct marketing".
2. Michael is at a party with a group of friends and he sees a very attractive girl. A friend approached her and said, "You see that boy there, it's a very good shot". This is named the "advertising".
3. Michael is at a party and sees a very attractive girl. He asks her phone number. The next day he called and said, "I am a very good shot". This is what we name "telemarketing".
4. Michael is at a party and sees a very attractive girl. He recognized and approaches her, he refreshes her memory by saying: "You remember that I am a very good shot?". This is named the "Customer Relationship Management (CRM)".
5. Michael is at a party and sees a very attractive girl. He stands up, arranges a little, approaches her and serves as a glass. He opens the door when she leaves, picks up his bag when he falls, offers her a cigarette and said, "I am a very good shot". This is what we name "public relations" or "public relations" (PR).
6. Michael is at a party and sees a very attractive girl. He invites all her girlfriends to dance, offer them a drink and laugh with ostensibly very spiritual jokes. The beautiful girl approach and say, "I feel that you are a very good shot". This is named "lobbying".
7. Michael is at a party and sees a very attractive girl. She approach him and said: "I heard you're a very good shot". This is named the "brand power".
8. Michael is at a party and see a super beautiful girl. He looks at her with his friends, doing very fine reflections, completely drunk, does nothing and return alone at home. This is named the "market reality"...



READY FOR THE FLUID DYNAMICS SEMINAR?
HELL YA!

basically .. when I look back, at college my professors were idiots, at the army, my superiors were idiots, and my many bosses at work were idiots...
... i'm sure now! The key of success is to be stupid!

* * *

A man is flying in a hot air balloon and realizes he is lost. He reduces height and spots a man down below. He lowers the balloon further and shouts: "Excuse me, can you tell me where I am?"

– The man below says: "Yes, you're in a hot air balloon, hovering 30 feet above this field."

– "You must be an engineer" says the balloonist.

– "I am" replies the man, "How did you know?".

– "Well!" says the balloonist, "Everything you have told me is technically correct, but it's no use to anyone!".

– The man below says: "You must be manager!".

– "I am!" replies the balloonist, "But how did you know?".

– "Well!", says the man, "You don't know where you are, or where you're going, but you expect me to be able to help. You're in the same position you were before we met, but now it's my fault!".

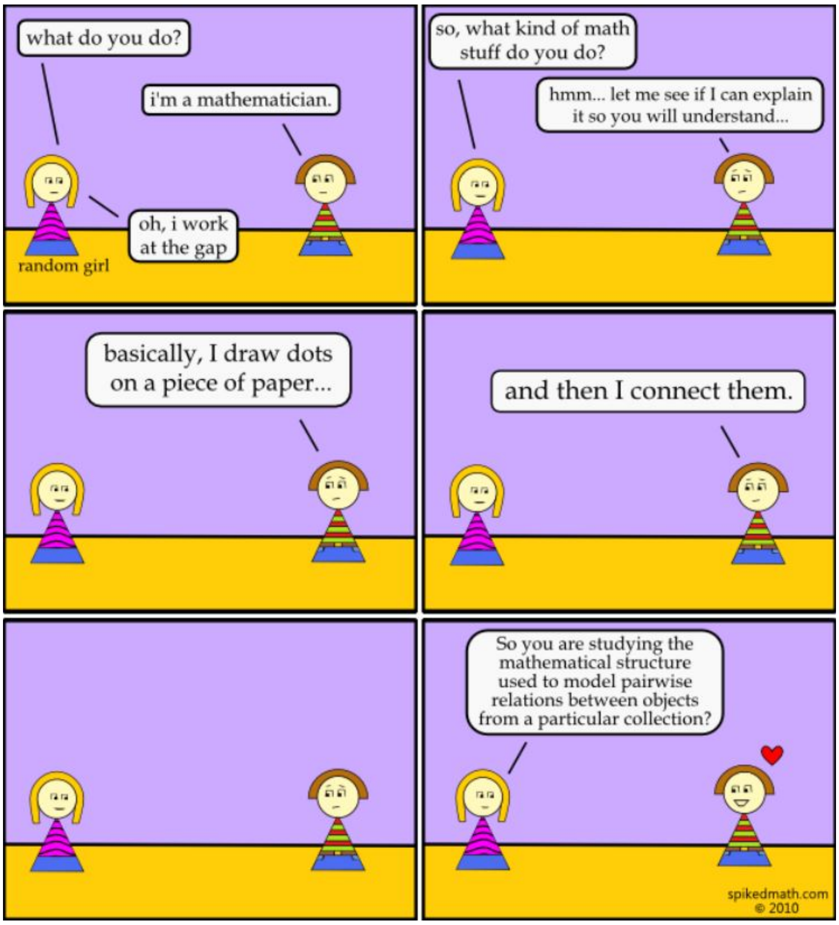
* * *

A man goes on a Saturday at a wedding in a Corsica small village. He's late and he drives as fast as possible on winding roads. Suddenly, after a turn, it must stop short, a flock of sheep occupies the entire road. The shepherd is there and slowly move his flock. The driver uses the horn of his vehicle several times without any effect. After a few minutes, the driver apostrophe the shepherd and says:

- "I'm late, I'm going to a wedding that will be followed by a barbecue, if I tell you how many sheep you have, you will you give me one of your sheep?"
- "For sure" said the shepherd, "I am not close to one".
- The driver takes his calculator and after a minute announce: "1233".
- "You won!" say the shepherd, "Choose your pet".

The driver designate one. The shepherd then ask:

- "If I find what is your profession, you give me back my beast?"
- "Of course!" say the driver, "I'm listening!".
- "You are a high level official public servant and you've done and high level administration school or another big school like this?".
- "You are right!" say the driver, "But how did you guess?".
- The shepherd: "Please give my dog back"



what do you do?
i'm a mathematician.
oh, i work at the gap
random girl
so, what kind of math stuff do you do?
hmm... let me see if I can explain it so you will understand...
basically, I draw dots on a piece of paper...
and then I connect them.
So you are studying the mathematical structure used to model pairwise relations between objects from a particular collection?

Links

This directory contains links in 7 categories all relating to science and that may interest the reader. Obviously under no circumstances we were paid in any form whatsoever for adding links in the list below!

- ✔ High-Quality website both in terms of design and content
- ✍ Content with developments and demonstrations
- ✉ Website with forum
- ✄ Scientific softwares, sharewares, freewares to download
- ➥ Books, publications, magazines, papers (to view or download)
- ✌ Cool/funny website
- ♥ Favourite website
- ☆ Must see!

If there were also three links to highlight of all this is Google, Wikipedia and YouTube that we owe many loans!

Remark

We have no responsibility for the persistence or accuracy of URLs for external or third-party Internet websites referred to in this textbook, and does not guarantee that any content on such websites is, or will remain, accurate or appropriate.

21.1. Exact Sciences

✔✍✄✌♥☆🇫🇷 ChronoMath, small chronology of mathematics, is an educational document that Serge Mehl is constantly renewing since 11988 (holocene calendar) as a math tutor in French Africa where he was cooperating for many years. More than 450 mathematicians (and their work) are reviewed ...! Must see!
http://www.chronomath.com

✉✄➡🇫🇷 This site offers mathematics news, an encyclopaedia with dictionary parts, biographies and formulas, as well as individual files on various mathematical topics and a forum. This site is particularly impressive with respect to the amount of information available for download.
http://www.bibmath.net

✔✍🇫🇷 A good site dealing with some relevant topics in physics (synophysics). The design could be reviewed in terms of navigation using frames ... but we must still focus on the content quality and it largely predominates.
http://www.sciences.univ-nantes.fr/physique/perso/blanquet/frame3.htm

✔✍✄🇫🇷 Many PDFs on algebra, geometry and analysis.
http://c.caignaert.free.fr

✔✍✄ arXiv is an archive for electronic preprints of scientific papers. The time elapsing between the time a researcher completes a project and when his work is published in a newspaper may be about a year. At the time scale of research it's a long time. The introduction of the arXiv is therefore a way to overcome this time and cost problem.
http://arxiv.org

✔✍✄🇫🇷 The multidisciplinary HAL open archive is intended for the deposit and the free dissemination of research level scientifical published and unpublished results and theses from French of foreign educational institutions, public or private laboratories. There is even scientific books published recently by prestigious French publishing houses.
http://hal.archives-ouvertes.fr

✔✉✄✌♥☆ Zooniverse and BOINC are two citizen science web portals owned and operated by the Citizen Science Alliance and respectively by the Berkeley Open Infrastructure for Network Computing. It is home to some of the Internet's largest, most popular and most successful citizen science projects (collaborative research by installing a software to share computing power, playing a game-like scientific problem to resolve a hard problem, recognize images content, etc.). If you found a solution or a scientific evidence in one of these projects, your name (or nickname) will be quoted in the corresponding scientific publication!
https://www.zooniverse.org + https://boinc.berkeley.edu

✔✉✄✍☆ MathDB is a community database of open problems in mathematics, designed to keep track of the rapid growth of AI-assisted mathematical breakthroughs. It's free to browse;

sign in to post and comment.
https://mathdb.com

21.2. Publishing/Magazines

✔✉➡♥☆🇫🇷 We can consider this proposed website as the equivalent of the previous, but for the French engineers. However, it is qualitatively better and there are approximately the same number of files but more homogeneous. The only regret is perhaps the access to certain elements which is not always easy the first time and also non-free.
http://www.techniques-ingenieur.fr

✔➡♥☆🇫🇷 The website itself is not great (which is a pity) but the magazine for which he offers to subscribe (against payment) is well for a visit for people who like mathematics and their actuality.
http://tangente.poleditions.com

✔➡♥☆🇫🇷 Excellent website with a huge resource (links directory) of electronic documentation dealing with mathematics only in French and English. The site contains links to the pages of the authors of the documents (if not it would require a considerable server ...).
http://mathslinker.chez-alice.fr

➡🇫🇷 This site contains an on-line library of publications in French of the greatest mathematicians of the 20th and 19th century. Must See!
http://matwbn.icm.edu.pl/wyszukiwarka.php

✔➡♥☆🇫🇷 Reprints of fundamentals works on mathematics, physics, history and philosophy of science.
http://www.gabay.com

✔➡♥☆🇫🇷 Eyrolles Editions - Excellent website containing numerous works of quality in English and French. This website propose the books of several publishers including Wiley, Springer, etc. It is worthwhile to go take a look in the sections "Mathematics" and "Physics" there are good things...
http://www.eyrolles.com

✔➡♥☆🇫🇷 Dunod Editions - Propose contemporary literature (under and postgraduate). The books of this publishing house are mostly excellent. Personally they are technically (but not pedagogically) my favourite, because often the developments are very detailed.
http://www.dunod.com

➡♥ Springer Editions - Propose scientific literature of PhD level. The site navigation is not easy because the choices are arranged a bit anyhow but if the proposed works are very technical

and high level ... very high level.
http://www.springer.de

➥♥☆🇫🇷 The NUMDAM program, led by MathDoc (UMS 5638 CNRS - UJF) on behalf of CNRS, provides retrospective digitization of mathematics funds published in France.
http://www.numdam.org

✔➥♥☆ Wrox Editions - Propose computer development books (expert level). As far as I know (and I think so), this publishing house is the worldwide reference in the field of books about programming languages.
http://www.wrox.com

✔♥☆ Cambridge University Press Editions - Propose also postdoc level scientific literature. Somewhat the equivalent of Springer Editions but the website structure is a little bit better. You can particularly appreciate the opportunity to subscribe for free to receive regularly their catalogue.
http://www.cambridge.org

✍➥♥☆🇫🇷 The Digital Library of France (BNF) offers a free download of the scientific literature (among others) whose copyrights have fallen after 75 years. The download system is not user friendly, but you can find very relevant works. PDFs are often more than 10 MB so take care if you have a slow Internet connection.
http://gallica.bnf.fr

✍➥♥☆ The Physical Review Letters (PRL) search engine (scientific papers) offers against registration and payment (sic) access to scientific research articles in theoretical and experimental physics published for over 100 years. The level of detail of the articles offered is often not very high but this is not the main objective for specialists.
http://prola.aps.org/search

✍➡☆🇫🇷 Lavoisier Editions - Very good publisher offering books in the highly specialized field of electronic, electrical, civil, computer engineering etc. You can also particularly appreciate the opportunity to subscribe for free to receive regularly their great catalogue. See especially the "Hermes Science" and "Tech & Doc" link of this publisher.
http://www.lavoisier.fr (http://www.editions-hermes.fr)

21.3. Associations

✌ myScience.ch gives an overview of science, research, universities, companies and other research centers in Switzerland. The site provides practical information on jobs, funding and lives in Switzerland and also science news to researchers, scientists, academics and anyone interested in science. It has a higher proportion of articles in German ... even in the French version...
http://www.myscience.ch

➡✌☆🇫🇷 The Rationalist Union aims to promote the role of reason in the intellectual debate as in the public debate, in front of all irrational excesses. It strives to make available to everyone the opportunity to access an intelligible conception of the world and the life. She strike for a State that remains secular and assume its function of protecting against all forms of indoctrination.
http://www.union-rationaliste.org

✍➡ The American Society of Mathematics is an association of professional mathematicians dedicated to the interests of research and teaching of mathematics, what it does in the form of various free publications and conferences, and prizes awarded to mathematicians.
http://www.ams.org

✍➡ The American Physical Society is a scientific society founded in May 20, 11899 (holocene calendar), based in the U.S., very active in the field of scientific research in physics.
http://www.aps.org

✍➡♥ The European Physical Society (EPS) is a non-profit organization whose purpose is to promote physics and physicists in Europe. This society propose a subscription to it's Europhysicsnews magazine and many other things.
http://www.eps.org

✍➡Retraction Watch is a watchdog platform that tracks retracted and corrected scientific papers to improve transparency and accountability in research. By documenting why studies are withdrawn and highlighting patterns of misconduct, errors, or systemic weaknesses, it helps scientists, journalists, and the public better understand how the self-correction process in science works. The raw data can be downloaded for free in a CSV file.
https://retractionwatch.com/

21.4. Jobs

☆ Here is a list of websites for job positions especially for swiss physicists and mathematicians ... (however a link is only for U.S. territory!). So the descriptions are often in German (...) and the job positions for the banking sector (who represents 10-15% of employment in Switzerland from what I know ...). Some offers are linked to more general sites like the famous jobup.ch actually well known in Switzerland.

- http://www.telejob.ch
- http://www.jobs.myscience.ch
- http://www.math-jobs.ch
- http://www.analyticrecruiting.com

21.5. Television/Radio

☆ Excellent website explaining with 3D animation many classical equipment of daily life designed and developed by engineering methods (motor, refrigerator , pump, etc.).
http://www.learnengineering.org

🇫🇷 C'est pas Sorcier: The famous french TV show (modern version in french of "Bill Nye the Science guy") about all sciences that almost all young french speaking have know or still discover!!
https://www.youtube.com/user/cestpassorcierftv

🇫🇷 Cité-Sciences: Viewing video-conferences, or listening to audiotapes on popular topics of physics and astronomy (+ others) popularized.
http://www.cite-sciences.fr

🇫🇷 On Canal Académie, academics, specialists in physics, mathematics, humanities, philosophy, sociology, law and jurisprudence, economics, politics and finance, history, geography and demography and political science will share their thoughts on the news and society developments.
http://www.canalacademie.com

And here is a small and non-exhaustive list of scientific YouTube channels that are scientifically quite reliable, managed by passionate individuals and of good post-production quality and especially very useful to understand better some of the complicated theorems and subjects treated in this textbook (most videos are of high-school level):

- https://www.youtube.com/user/ScienceEtonnante (en, David Louapre)
- https://www.youtube.com/user/Micmaths (fr, Mickaël Launay)
- https://www.youtube.com/user/physicswoman (en, Dianna Cowern)
- https://www.youtube.com/user/1veritasium (en, Derek Muller)
- https://www.youtube.com/channel/UCYO_jab_esuFRV4b17AJtAw (en, Grant Sanderson)
- https://www.youtube.com/user/fauxsceptique(fr, Christophe Michel)
- https://www.youtube.com/channel/UC7_gcs09iThXybpVgjHZ_7g (en, Matt O'Dowd)
- https://www.youtube.com/user/mathdude2012 (en, Andrey Kopot)
- https://www.youtube.com/user/LearnEngineeringTeam (en, Sabin Mathew)
- https://www.youtube.com/@jkzero (en, Dr. Jorge S. Diaz)

21.6. Other Sciences

✔✉➥✌☆🇫🇷 Futura-Sciences is website for the popularization of pure and exact sciences with news about sciences and technologies, issues on many topics, scientific forums with debate and discussions ... (the physics forum is especially well attended).
http://www.futura-sciences.com

✔✉➥✌☆ Physics Forum is consider as the world's largest physics community. There is a ton of discussions on many subjects answered with quality by the community. This forum is also considered as the partner forum of this e-book (even if they consider my book as spam...) as I don't have time to answer to questions anymore for free by e-mail.
http://www.physicsforums.com

✔✉➥✌☆ Stack Exchange is a network of question-and-answer websites that cover a broad range of topics in various fields, including mathematics, physics, programming, and many others. It was created in 2008 and has since become one of the largest online communities for people to ask and answer questions. Each website in the network is centered around a specific topic, and users can ask and answer questions, vote on the best answers, and even edit each other's responses. The network also includes features such as badges, reputation points, and a system for suggesting edits, which incentivize users to contribute high-quality content.
http://www.stackexchange.com

✔✉➥✌☆ Stack Overflow is one of the largest and most popular websites in the Stack Exchange network. It was launched in 2008 and is focused on programming and software development-related questions and answers. The website provides a platform for developers and programmers to ask and answer technical questions, share their knowledge and experience, and find solutions to coding problems. It has become a go-to resource for many developers, as it has a vast collection of questions and answers on a wide range of programming topics, from basic coding concepts to complex algorithms. Additionally, the website has a reputation and voting system that allows users to upvote the most helpful answers, helping to ensure that the best answers rise to the top.
http://www.stackoverflow.com

✔✍✉✄➥✌♥☆🇫🇷 Astrosurf is a portal of links (directory) for French amateur astronomers. There is also astronomy forums astronomy, announcements, free astronomy websites hosting, ephemeris and all the clubs and associations of French astronomy. You can particularly found the famous site of Thierry Lombry (here).
http://www.astrosurf.com

✔➥🇫🇷 The C.E.A. is the French Commissariat à l'Énergie Atomique. The site offers news and interesting files on particular areas of advanced physics. One can also find free educational resources for teachers (slide shows and posters).
http://www.cea.fr

✌☆ Here is a site that, if I was a child, would have made me happy ... and the misery of my

parents. It's not so much the content that is interesting but especially the online store (eStore) which offers a hundred gadgets and educational games for passionate of science. Attention to not spend too much!
http://www.xump.com

✌☆ For years, the cartoons of S. Harris have added humor to innumerable magazines, books, newsletters, ads and web sites in the field of sciences. Enjoy!
http://www.sciencecartoonsplus.com

21.7. Softwares/Applications

✔♥☆ Rosetta Code is a programming chrestomathy site. The idea is to present solutions to the same task in as many different languages as possible, to demonstrate how languages are similar and different, and to aid a person with a grounding in one approach to a problem in learning another. Rosetta Code currently has 861 tasks, 208 draft tasks, and is aware of 671 languages.
https://rosettacode.org

✔✄♥☆ TeXmaker is a free, cross-platform LaTeX editor. LaTeX is a typesetting system that is widely used in academia and scientific publishing to produce high-quality, professional-looking documents, particularly in the fields of mathematics, physics, and computer science. TeXmaker provides a user-friendly interface for creating and editing LaTeX documents, making it easier for users to get started with LaTeX. Some of its features include a built-in PDF viewer, multi-language support, and a wizard for creating new documents. TeXmaker is also highly customizable, with options for configuring keyboard shortcuts, syntax highlighting, and more. It is a popular choice among LaTeX users due to its ease of use, customizable interface, and support for a wide range of operating systems, including Windows, macOS, and Linux.
http://www.xm1math.net

✔✄♥☆ Matcha LaTeX Editor is a web-based LaTeX editor and provides a user-friendly interface for creating and editing LaTeX documents, making it easier for non-experts to get started with LaTeX. Some of its features include real-time collaboration, live preview, and templates for various document types. It's drawing tool that generates TikZ code is far above its competitors (LaTeXDraw, Overleaf, etc.).
https://www.mathcha.io

✔✄♥☆ Mathpix is an OCR (Optical Character Recognition) that allows users to take a photo of a handwritten or printed math equation, table or molecule and convert it into a LaTeX expression, which can then be edited and rendered in various formats. The tool is designed to help students, teachers, and researchers save time and effort when working with mathematical expressions and equations, and to eliminate the need to manually transcribe equations into a typesetting program.
https://mathpix.com

✔✄♥☆ The Integral Calculator lets you calculate integrals and antiderivatives of functions online and Derivative Calculator lets you calculate derivatives of functions online — for free! Both websites show the full working (step by step integration or step by step derivation). All common integration and derivation techniques and even special functions are supported. The Integral Calculator supports definite and indefinite integrals (antiderivatives) as well as integrating functions with many variables. The Derivative Calculator supports computing first, second, . . . , fifth derivatives as well as differentiating functions with many variables (partial derivatives), implicit differentiation and calculating roots/zeros. You can also check your answers! Interactive graphs/plots help visualize and better understand the results.
https://www.integral-calculator.com + https://www.derivative-calculator.net

✔✄♥☆ Minitab is the leading software for engineers working in industry and applying

statistical process control (see section Industrial Engineering page 8673) as part of their work or making any statistical study in the context of R& D.
http://www.minitab.com

✔✄♥☆ Isograph is an excellent suite of software for engineers working in industry and applying the techniques of preventive maintenance (reliability, FMEA) and decision support (see section Game and Decision Theory page 7376).
http://www.isograph-software.com

✔✄♥☆ The ReliaSoft company develops in my opinion the best softwares on the market for reliability and quality assurance engineers. Their software is used by the best engineering companies worldwide. Overall their software are real small diamonds (particularly Weibull++).
http://www.reliasoft.com

✔✄☆ JMP is for me the best known software for design of experiments at this date. His pedagogical structured and the very good available documentation (books) with mathematical proofs of the approach used by the software is well appreciated.
http://www.jmp.com

✔✄♥☆ Official website of the excellent Maple symbolic computation software used for many examples in the different chapters of this textbook. The website also offers lots of documentation and plugins to download.
http://www.mapleapps.com

✔✄☆ Official website of MATLAB® calculation and simulation software. I'm not especially a fan but I must admit this is an essential tool in some businesses, especially for the SimuLink part and R&D Engineering. This is somewhat a "must have" for engineers as well as LabView.
http://www.mathworks.com

✔✄☆ Official website of the company Statistica. A worldwide reference in the field of statistical analysis, data mining and statistical process control that stands a priori in a handkerchief with IBM SPSS.
http://www.statsoft.com

✔✄♥☆ COMSOL Multiphysics (formerly FEMLAB) is an excellent interactive environment for the modelling of industrial and scientific applications based on partial differential equations (PDEs) using finite element methods (more easy to use than ANSYS). A must have for engineers and researchers (for those who can afford to buy the license of course ..)!
http://www.comsol.fr

✔✄♥☆ Palisade @Risk is an add-in suite for Microsoft® Excel® and Microsoft Project for probabilistic simulation (Monte Carlo and Latin Hypercube). It's joint integration with Microsoft Project and Microsoft® Excel® and its calculations modules based on genetic algorithms, neural networks and its add-in of decision theory makes it a coveted tool for high executive officers of large companies (NASA and Lockheed Martin use it for major projects) and high level engineers in the field finance, quality, project management and production.
http://www.palisade.com

✔✄♥☆ The Decision Analysis software edited by TreeAge (DATA) allows users to build, analyse and distribute tree analysis, Markov models and influence diagrams. The DATA models incorporate visually quantitative and qualitative aspects related to business decisions to provide a tool to assist in projects during analysis of complex risks.
http://www.treeage.com

✔✄♥☆ MathType is a powerful equation editor (software used for this website) to import/export MathML or TeX or you can run in it stand-alone application. With a toolbar, it also fits perfectly with the programs of the Microsoft Office 2003-2013 suite (Word, Excel, PowerPoint), but also with 500 other softwares (specifically math softwares, or not). At the difference with LaTeX2ε you will not loose hours to solve compatibility and compilation issues.
http://www.wiris.com

✔✄☆ Scilab (contraction of Scientific Laboratory) is a free software, developed at INRIA Rocquencourt (France). It is a numerical computing environment that enables fast numeric resolutions and graphics commonly encountered in Applied Mathematics for people or small business having not enough money to buy MATLAB®.
http://www.scilab.org

✄☆ Official website of the famous dynamic geometry software: Cabri (worldwide reference in this domain) primarily destinated for the learning of geometry in schools. It can animate geometric figures, unlike those drawn on the blackboard. It comes to plane geometry or for geometry in 3D. It is the ancestor of all dynamic geometry software.
http://www.cabri.com

✄♥☆🇫🇷 Website of a math teacher who developed a very good freeware for many relevant charts, integration calculations, simulations of statistics and probabilities easily and playfully in the classroom (College level).
http://www.patrice-rabiller.fr

✄☆ ACDLabs develops the excellent Chemsketch software for molecules modelling and design (2D, 3D) with access to certain physical and chemical properties. This is a very useful tool also to prepare handouts or scientific articles (publications).
http://www.acdlabs.com

✄☆♥ MolView is an intuitive, Open-Source web-application to make molecular chemistry science more awesome!
http://molview.org

✄☆ Maxima is a computer algebra freeware (a Maple like software), falling under GNU GPL under the package Macsyma, the symbolic calculation software originally developed for the needs of U.S. Department of Energy. Maxima can do arithmetic, polynomials, matrices, integration, derivation, the calculation of series, limits, resolutions of systems of differential equations, etc.
http://maxima.sourceforge.net

✄☆ SPSS (Statistical Package for the Social Sciences) is a priori the most widely used software in companies in Switzerland for statistical analysis of data because it has an impressive

number of tests as well as many business packages. Because of its price and its owner (IBM) can be regarded as the premium solution of Statistics.
https://www.ibm.com/products/spss-statistics

✄♥☆ `R` is a free powerful language and environment for statistical computing and graphics. R provides a wide variety of statistical (linear and non-linear modelling, classical statistical tests, time-series analysis, classification, clustering, ...) and graphical techniques, and is highly extensible. One of R's strengths is the ease with which well-designed publication-quality plots can be produced, including mathematical symbols and formulae where needed.
http://www.r-project.org

✄☆ LabVIEW (Laboratory Virtual Instrument Engineering Workbench) is a powerful visual tool (graphical programming language) developed by National Instruments to control measures instrument or robots from a PC and used by a lot of companies worldwide (particularly by engineers).
http://www.ni.com/labview

✄♥☆ Symbolab is an advanced math education tool. It allows users to learn, practice and discover math topics using mathematical symbols and scientific notations as well as text. Symbolab provides automated step by step solutions to algebraic, trigonometric and calculus topics covering from middle school through college. Symbolab offers a wealth of smart calculators including: equations, simultaneous equations, inequalities, integrals, derivatives, limits , tangent line, trigonometric equations, functions and more. The stated goal of the site is to make scientific content universally accessible by expanding the searchable data space onto scientific notations, expressions, equations and formulas
https://www.symbolab.com

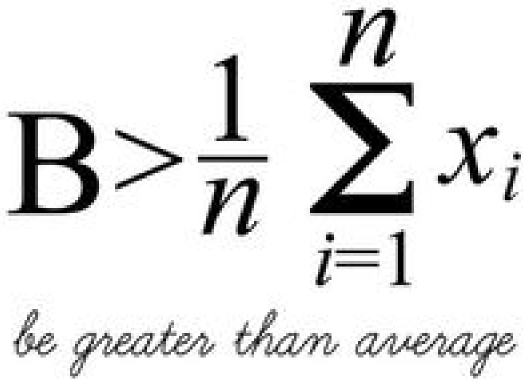
And finally a small list of some great "scientific" apps for iPhone/iPad:

- **Microsoft OneNote**: To take notes and write equations in pseudo LaTeX easily and sync them with your computer and the cloud.
- **iAnnote**: Great PDF reader with a lot of functions to annotate and modify your textbooks and scientific publications and handle huge books.
- **WeatherProHD**: For people that like meteorology and weather forecasts presented and beautiful and professional way with a lot of options.
- **Solar Weather**: For people interested to know our Sun activity based on the K-index.
- **Earthquake**: For people interested to know where, at what depth and at what magnitude an earthquake happened anywhere in the world in real-time.
- **Volcanoes**: For people interested to know what kind of volcanic eruption and with all most important details happened around the world in real-time!
- **Earthnow**: This NASA's app helps to visualizes recent global climate data from Earth Science satellites, including surface air temperature, carbon dioxide, carbon monoxide, ozone, and water vapour as well as gravity and sea level variations.
- **Analyser**: For those that want to run R or Python™ on their iPad and iPhone. Incredible app to do data science while travelling!
- **TeX Writer**: So far the best LaTeX app we know so you can write equations and documents on your mobile devices!
- **Telesat**: To identify or anticipate in the night sky the pass trough of some well-known satellites.
- **ISS Detector**: Same idea as for Telesat but for the International Space Station.
- **Flightradar24**: Same ideas as for Telesat and ISS Detector but for almost all civilian airplanes (but the free version show the airplanes with a small shift for security reasons).
- **Sun Info**: An app that helps you to anticipate the position of the Sun and Moon on many years and also summer/winter solstice, next eclipses and so on...
- **Stellarium**: As its name indicates it, it is a beautiful real time and complete stellarium to gaze at the stars, galaxies, constellations and also some satellites.
- **C. Anatomy 19**: An app (quite expensive with monthly/yearly subscription) to discover in high 3D resolution the inside of the human body.
- **EarthViewer**: An app to discover and play with the continents drifts of Earth across the time.
- **MathStudio**: A very powerful arithmetic and algebraic calculator that has calculation options similar to that Maple.

- **PCalc Lite**: A very nice an intuitive complete arithmetic calculator (but obviously less powerful than MathStudio!).
- **Molecules**: A 3D molecules viewer where you can download molecules from an online database.
- **E Numbers**: E numbers gives you the codes for substances that are permitted to be used as food additives.
- **iCircuit**: A nice app to create simple electronic circuits and simulate them! Very good to learn the basics of electronics while in holidays without the need of real physical components.
- **Electronic TB**: An app that provides a quite important (exhaustive) list and calculators for many electronic components, including many of their technical properties!
- **Symbolab**: This is just the app equivalent of the already previously mentioned website of the same name!

22

Quotes



We summarize here the different quotes that are in the various chapters of this textbook. We added also below some quotes that may be useful when debating some scientifically illiterate people who use quotes to back-up their claims (as these people assume that a quote has a scientific evidence level other than zero...).

> *If you steal from one author, it's plagiarism; if you steal from many, it's research!*
>
> Wilson Mizner

> *We are trying to prove ourselves wrong as quickly as possible, because only in that way can we find progress!*
>
> James D. Eckard

> *In mathematics, you don't understand things. You just get used to them.*
>
> John von Neumann

> *The statements of science are not what is true and what is not true, but statements of what is known with different degrees of certainty.*
>
> Richard Feynman

> *You can't convince a believer of anything; for their belief is not based on evidence, it's based on a deep seated need to believe.*
>
> Carl Sagan

> *The Universe is not fine-tuned to us: We are fine-tuned to our particular Universe!*
>
> Victor J. Stenger

> *We know very well the wisdom of crowds! It was the one who elected Hitler in 11933 (holocene calendar) and Trump in 12016 (holocene calendar).*
>
> ?

> *Since Newton, mankind has come to realize that the laws of physics are always expressed in the language of differential equations.*
>
> Steven Strogatz

> *All things are poisons, for there is nothing without poisonous qualities. It is only the dose which makes a thing poison!*
>
> Paracelsus

> *Men never do evil so completely and cheerfully as when they do it from religious conviction!*
>
> Blaise Pascal

> *Understanding how a rainbow works doesn't make it less beautiful, it makes it more beautiful. That is Science!*
>
> Richard Dawkins

> *If you can explain a God without a creator, you can explain a Universe without a creator...*
>
> ?

> *The best way to learn is to teach.*
>
> Frank Oppenheimer

> *Without faith, God is nothing. Without science, man is nothing.*
>
> John Aubrey

> *If we could do things by common sense, we wouldn't need physicists.*
>
> Richard Dawkins

> *Intelligence is not what we know but what we do when we don't know.*
>
> Jean Piaget

> *If a religion had even one true evidence beyond reasonable doubt, there would be no other religions!*
>
> ?

> *Religion is an insult to human dignity. With or without it, you'd have good people doing good things and evil people doing evil things. But for good people to do evil things, it takes religion!*
>
> Steven Weinberg

> *With four parameters I can fit an elephant.*
>
> John Von Neumann

> *A scientist will read dozens of books in his lifetime, but still known that he has a lot more to learn. A religious fanatic barely reads one book, and think that they know it all.*
>
> ?

> *I think of my lifetime in physics as divided into three periods. In the first period... I was in the grip of the idea that Everything is Particles... I call my second period Everything is Fields. ... Now I am in the grip of a new vision, that Everything is Information.*
>
> John Archibald Wheeler

> *Religion is the practice of using nonsense, in order to explain ignorance.*

?

> *Nothing can create something all the time due to the laws of quantum mechanics, and it's fascinatingly interesting!*

Lawrence M. Krauss

> *Let no one ignorant of geometry enter here!*

Plato

> *Everything is just some form of first order Taylor Expansion!*

?

> *Computers are like humans - they do everything except think.*

John von Neumann

> *SCIENCE is not defined by what we believe. IT IS NOT a belief system. It has no religious doctrine! It's just an intellectual investigation method that rejects claims that have no supporting experimental reproducible evidence.*

?

> *Extraordinary claims require extraordinary evidence.*

Carl Sagan

> *I have your letter and the best thing I can do is refer to my published works, both scientific and popular. The creationist movement is lead by a dishonest bunch of operators and misquotation is the hall mark of their work. Responding to them is time wasting and a letter would not be adequate to put your questions to rest. There are some things best ignored and the stupidity of these so called religious fanatics continues to astonish me.*

Richard Leakey

> *Most people don't really want the truth; they just want reassurance that what they already believe, is the truth.*

L. Aron Nelson

> *The reason there is a conflict between science and religions is that science keep disproving the things religions claims to be true or accurate.*
>
> ?

> *He who loves practice without theory is like the sailor who boards ship without a rudder and compass and never knows where he may cast.*
>
> Leonardo da Vinci

> *The Earth is not fitted to us, we are fitted to the Earth.*
>
> ?

> *We measure the degree of intelligence of an individual by the quantity of incertitudes he can handle.*
>
> Emmanuel Kant

> *I don't even like the multiverse but if Nature tells me that's the case, and the laws of physics are accidental, I've got to live with it.*
>
> Lawrence M. Krauss

> *Insurance is when you buy coverage when you need it. Reality is when you buy the option of going to court for coverage when you need it.*
>
> ?

> *Physics is like sex. Sure it may have some practical results, but that's not why we do it.*
>
> Richard Feynman

> *Mathematics is not only real, but it is the only reality. That is that entire universe is made of matter, obviously. And matter is made of particles. It's made of electrons and neutrons and protons. So the entire universe is made out of particles. Now what are the particles made out of? They're not made out of anything. The only thing you can say about the reality of an electron is to cite its mathematical properties. So there's a sense in which matter has completely dissolved and what is left is just a mathematical structure.*
>
> Martin Gardner

> *Each generation of scientists stands upon the shoulders of those who have gone before.*

Owen Chamberlain

> *In precisely built mathematical structures, mathematicians find the same sort of beauty others find in enchanting pieces of music, or in magnificent architecture. There is however, one great difference between the beauty of mathematical structures and that of great art. Music by Mozart, for instance, impress greatly even those who do not know musical theory; the cathedral in Cologne overwhelms spectators even if they know nothing about Christianity. The beauty in mathematical structures, however, cannot be appreciated without understanding of a group of numerical formulae that express laws of logic. Only mathematicians can read "musical scores" containing many numerical formulae, and play that "music" in their hearts.*

Kiyoshi Ito

> *In physics anything that can happen (meaning has a non-zero probability of occurring) eventually will happen!*

?

> *You don't have to burn books to destroy a culture. Just get people to stop reading them.*

Ray Bradbury

> *Science doesn't know everything, religion doesn't know anything!*

L. Aron Nelson

> *The science of today is the technology of tomorrow.*

Edward Teller

> *Science is different to all the other systems of thought... because you don't need faith in it, you can check that it works!*

Brian Cox

> *Ignorance more frequently begets confidence than does knowledge: it is those who know little, not those who know much, who so positively assert that this or that problem will never be solved by science.*

Charles Darwin

> *Differentiation is a science, Integration is an art.*

?

> *Finding proofs of your delusions in simple coincidences of life is a very desperate attempt of conviction...*

Martino Villadari

> *The fact that a believer is happier than a septic is no more to the point than the fact that a drunken man is happier than a sober one.*

George Bernard Shaw

> *I don't want to believe, I want to know.*

Carl Sagan

> *Science knows it doesn't know everything, otherwise it would stop.*

Dara Ó Brian

> *Science is just imagination in straitjacket.*

Richard Feynman

> *The greatest enemy of knowledge is not ignorance, is the illusion of knowledge!*

Stephen Hawking

> *Without data you are just another person without opinions, but without mathematics you are just a data collector.*

?

> *I have no special talents, I am only passionately curious.*

Albert Einstein

> *People keep saying "Science doesn't know everything!". Well, science know it doesn't know everything; otherwise it would stop.*

Dara Briain

> *The only way to learn Mathematics is to do Mathematics.*
>
> Paul Halmos

> *The scientist is not a person who gives the right answers; he is one who asks the right questions.*
>
> Claude Levi-Strauss

> *One can't prove that God doesn't exists, but Science makes God unnecessary.*
>
> Stephen Hawking

> *The power of numbers was much more respected among us when we knew nothing about them..*
>
> Voltaire

> *To reflect is to disturb one's thoughts.*
>
> Jean Rostand

> *If you are stupid how can you possibly realize that you are stupid?.*
>
> John Cleese

> *If you don't make mistakes, you're not working on hard enough problems. And that's a big mistake.*
>
> Frank Wilczek

> *Success relies on the success of those who have preceded us.*
>
> ?

> *Between quantity and quality there is geometry.*
>
> Brigitte Le Roux, Henry Rouanet

> *Practice should always be based upon a sound knowledge of theory.*
>
> Leonardo da Vinci

> *It doesn't matter how beautiful your theory is, it doesn't matter how smart you are! If it doesn't agree with experiment, it's wrong!*
>
> Richard Feynman

> *To call in the statistician after the experiment is done may be no more than asking him to perform a post-mortem examination: he may be able to say what the experiment died of...*
>
> Ronald Fisher

> *Errors using inadequate data are much less than those using no data at all!*
>
> Charles Babbage

> *Details make perfection, and perfection is not a detail.*
>
> Leonardo da Vinci

> *Ignorance is a virus. Once it starts spreading, it can only be cured by reason. For the sake of humanity, we must be that cure!*
>
> Neil Degrasse Tyson

> *The art of doing mathematics consists in finding that special case which contains all the germs of generality.*
>
> David Hilbert

> *If you think education is expensive, try ignorance.*
>
> Derek Bok

> *Tell me and I forget, teach me and I remember, involve me and I learn.*
>
> Benjamin Franklin

> *An expert is a person who has found out by his own experience all the mistakes that one can make in a very narrow field.*
>
> Niels Bohr

> *What you can imagine depends on what you know.*
>
> Daniel C. Denett

> *Any sufficiently advanced technology is indistinguishable from divinity.*
>
> Arthur C. Clarke

> *What one man calls God, another call it the Laws of Physics.*
>
> Nikola Tesla

> *The only person you need to be better than is the person you were yesterday!*
>
> ?

> *Great minds discuss ideas. Average minds discuss events. Small minds discuss people.*
>
> Eleanor Roosevelt

> *Be less curious about people and more curious about ideas.*
>
> Marie Curie

> *Creativity is intelligence having fun.*
>
> Albert Einstein

> *With enough of us, around the world, we'll not just send a strong message opposing the privatization of knowledge - we'll make it a thing of the past.*
>
> Aaron Swartz

> *The idea of a personal God is quite alien to me and seems even naive.*
>
> Albert Einstein

> *When you move your focus from competition to contribution life becomes a celebration. Never try to defeat people, just win the hearts.*
>
> Buddha

> ❞ *Math is the language of the Universe. So the more equations you know, the more you can converse with the cosmos.* ❞

Neil Degrasse Tyson

> ❞ *The whole trouble with the world is that the stupid are cocksure, and the intelligent are full of doubt.* ❞

Bertrand Russell

> ❞ *Some men see things as they are and ask why. Others dream things that never were and ask why not.* ❞

Gerge Bernard Show

> ❞ *Statistics is the grammar of science.* ❞

Karl Pearson

> ❞ *If you can't explain it to a six year old, you don't understand it well enough yourself.* ❞

Albert Einstein

> ❞ *Man is the most insane species. He worships an invisible God and destroys a visible Nature. Unaware that the Nature he is destroying is this God he is worshipping.* ❞

Hubert Reeves

> ❞ *If you can't measure it, you can't improve it!* ❞

Willima Thomson (Lord Kelvin)

> ❞ *Once you stop learning, you start dying.* ❞

Albert Einstein

> ❞ *There is only one good, KNOWLEDGE, and one evil, IGNORANCE.* ❞

Socrates

> *The purpose of argument, should not be victory, but progress.*

?

> *Science is the poetry of reality!*

Richard Dawkins

> *Real science can be far stranger than science fiction and much more satisfying.*

Sthepen Hawking

> *You don't understand the basic assumptions of your own culture if your own culture is the only culture you know.*

Alan Watts

> *The ones who are crazy enough to think that they can change the world are the ones who do!*

Elon Musk

> *The noblest pleasure is the joy of understanding!*

Leonardo da Vinci

> *Doubt is the father of invention!*

Galileo Galilei

> *It is easy to lie with statistics, but easier to lie without them.*

Fred Mosteller

> *What can be asserted without evidence can be dismissed without evidence.*

Christopher Hitchens

> *Religion is a culture of faith; science is a culture of doubt.*

Richard Feynman

> *The sciences do not try to explain, they hardly even try to interpret, they mainly makes models. By a model is meant a mathematical construct which, with the addition of certain verbal interpretations, describes observed phenomena. The justification of such a mathematical construct is solely and precisely that it is expected to work-that is, correctly to describe phenomena from a reasonable wide area.*

John von Neuman

> *You can beat 100,000 scholars with one fact, but you will very likely never beat an idiot even with 100 facts.*

?

> *No amount of peer-reviewed evidence will ever persuade an idiot, all the more if the latter is scientifically illiterate and doesn't master top level statistical calculations and the subtleties of the scientific method.*

?

> *The most important questions in life are indeed, for the most part, really only problems of probability.*

Pierre Simon de Laplace

> *The problem in society is not kids not knowing science. The problem is adults not knowing science. They outnumber kids 5 to 1, they wield power, they write legislation. When you have scientifically illiterate adults, you have undermined the very fabric of what makes a nation wealthy and strong.*

Neil deGrasse Tyson

> *Even a rough estimate, even a false one, is better than no estimate at all.*

?

> *Sooner or later the moment arrives when a decision must be made which is neither certain, neither suitable, nor popular, but it must be taken, because it is right.*

Martin Luther King

> *We have uncovered wonders undreamt by our ancestors who first speculated on the nature of those wondering lights in the night sky. We've crossed the solar system and sent ships to the stars. But we continue to search. We can't help it! A central element of the human future, lies far beyond the Earth. If we crave some cosmic purpose, then let us find ourselves a worthy goal...*

Carl Sagan

> *The way to cope with the future is to create it!*

Ilya Prigogine

> *Science doesn't tell us what to think but sometimes it tells us what we can no longer believe.*

Etienne Klein

> *A religious belief without dogma is not possible and science is not compatible with any dogma. So science can only be incompatible with religious beliefs.*

?

> *Philosophy debates God, maths ignores him, climatology doesn't need him, physics can't find him, biology contradicts him, logic kills him!*

Bill Flavell

> *Being a statistician means never having to say you are certain!*

?

> *If you are not a professional active scientist, and you disagree with scientists about Science, it's actually not a disagreement! You're just wrong!! Science is not truth. Science is finding the evidence. When science changes its opinion, it didn't lie to you. It learned more!*

?

> *Logic is the art of going wrong with confidence.*

Joseph Wood Krutch

> *Most of our so-called reasoning consists in finding arguments for going on believing as we already do.*

James Harvey Robinson

> *Truth is a word that oddly is used most by those who spread lies, that they themselves know to be lies!*

?

> *As a scientist (and atheist) you will often be hated by all those who believe in fairy tales and think that their opinions, anecdotes, circular logic and scientific illiteracy are worth it, but those who stands firm to the Scientific Method and to the precautionary principle will be saved and will help to save the haters. Comforting lies have always and are still taking the elevator and the Scientific Method takes the stairs, the lies will come first but one day or another the Science will always catch up with its unpleasant evidence.*

> *Not doubt, certainty is what drives one insane.*

Friedrich Nietzsche

> *Probability theory is nothing but common sense reduced to calculation.*

Pierre Simon de Laplace

> *The true logic of this world is in the calculus of probabilities.*

James Clerk Maxwell

> *When people say "The reason you can't trust science is that scientists used to say <thing that turned out be wrong> but now they say <different thing>", they are actually explaining why science works so well!*

Matt Blaze

> *Nature wants* 5 *of your* 7 *children dead. It wants you dead by* 50*. Everything better than that is brought to you by science and technology.*

David Frum

> *In science nothing can be proven at* 100% *but* 98% *of statistical evidence in science will always be better than the* 0% *evidence of any of the* 28,000 *religions and their* 3,000 *gods.*

?

> *All science is either physics or stamp collecting!*

Ernest Rutherford

> *Ce que nous observons, ce n'est pas la Nature en soi, mais la Nature exposée à notre méthode d'investigation.*

Werner Heisenberg

> *The Art and Science of asking questions is the source of all Knowledge.*

Thomas Berger

> *Mathematics is not a deductive science - that's a cliché. When you try to prove a theorem, you don't just list the hypotheses, and then start to reason. What you do is trial and error, experimentation, guesswork. You want to find out what the facts are, and what you do is in that respect similar to what a laboratory technician does!*

Paul Halmos

> *A theory which is not refutable by any conceivable event is non-scientific. Irrefutability is not a virtue of a theory (as people often think) but a vice.*

Karl Popper

> *What causes the universe to pop out of nothing? No cause is needed. If you have a radioactive atom, it will decay, and quantum mechanics gives the decay probability in a given interval of time, say, a minute. There is no reason why the atom decayed at this particular moment and not another. The process is completely random. No cause is needed for the quantum creation of the universe.*

Alexander Vilenkin

> *There is a fundamental difference between religion, which is based on authority, [and] science, which is based on observation and reason. Science will win because it works.*

Stephen Hawking

> ❞ *Science is a differential equation. Religion is a boundary condition.* ❞
>
> Alan Turing

> ❞ *The discovery that individual events are irreducibly random is probably one of the most significant findings of the twentieth century. ... for the individual event in quantum physics, not only do we not know the cause, there is no cause! The instant when a radioactive atom decays, or the path taken by a photon behind a half-silvered beamsplitter are objectively random.* ❞
>
> Anton Zeilinger

> ❞ *The emergence of life is ultimately a chemical process. If the conditions are right, life will emerge. I see no need for an initial push from a creator god.* ❞
>
> Didier Queloz

quote 22.0:9346.#94

> ❞ *Everything is a sign or miracle when you don't understand Physics.* ❞

> ❞ *The question of the truth of a religion is one thing, but the question of its usefulness is another. I am as firmly convinced that religions do harm as I am that they are untrue.* ❞
>
> Bertrand Russell

Changelog

This is a detailed changelog of the book for people interested to see how this textbook has evolved (to keep in touch with new releases send us an e-mail to subscribe to the newsletter), of course the years are based on the Holocene calendar:

- **May 12002**
    - Definitions (science, law, theorem, postulate, axiom, corollary, ...)
    - Operations of addition, subtraction, multiplication, division, power
    - Concept of Numbers (integers, relative real, fractional, complex algebra, abstract,...)
    - Domain of definition of variables
    - Arithmetic polynomials
    - Absolute value
    - Binary relations, order relations
    - Gamma Function Euler, Euler's constant
    - Electromagnetic wave equation, the wave speed, speed of the light, transported energy
    - Introduction to Optics
    - Rule of three, percentages
    - Net quantities, the cost price of purchase, indices, sale prices, brut prices, net profit, net price, assets
    - Simple and compound interest, late and early payments
    - Portfolio management (decision criteria, goodwill, return on investment)
    - Markowitz Model (utility function, selection criteria)
    - Vocabulary about Stock Exchange
    - Plasma Frequency
    - Probability (universe, events, axioms)
    - Combinatorial Analysis
    - Statistics (discrete variables, continuous variable, standard deviation, variance and covariance)
    - Distribution Functions (discrete uniform law, Bernoulli's law, binomial law, hypergeometric law, multinomial law, Poisson's law, Gauss-Laplace law, Cauchy's law, beta law, gamma law, chi-square law, Student's law)
    - Estimator, correlation

  - Matrix of covariance
  - Statistical adequation tests

- **June 12002**
  - Introduction Set Theory (Zermelo-Fraenkel theory, inclusion, complementarity, intersection, union, product, empty set
  - Arithmetic, harmonic, geometric, quadratic averages
  - Univocity
  - Logarithmic and exponential functions
  - Golden ratio
  - Introduction to Fourier series
  - Coulomb's law, electrostatic field, electrostatic potential
  - Ampere's Theorem
  - Biot-Savartlaw, magnetic field, magnetic induction
  - Maxwell's equations
  - Dimensions in euclidean and fractal geometry
  - One-dimensions, two-dimension, three-dimension Geometric shapes
  - Pythagorean theorem
  - Physical units systems
  - The principle of least action and energy conservation
  - Position, velocity and acceleration
  - Continuity equation
  - Bernoulli Equation
  - The Doppler effect
  - Restrained Relativity, invariance principle, Lorentz transformations (time, length, velocity addition, increase in mass, Minkowski space-time)
  - General relativity (world line, punctual event, inertial particles, null cones, space-time vectors spaces and curved planes, metric tensor)
  - Heisenberg principles of uncertainty, Schrödinger equation, Wave probability density
  - Introduction to superstrings

- **July 12002**
  - Creating of Table of Contents
  - Visual representations of functions
  - 2nd degree polynomials and roots
  - Operator of vector and scalar fields (gradient, nabla, divergence, curl, laplacian)
  - Vector Analysis (concept of arrow, set of vectors, scalar multiplication, vector space, linear combinations, generating families, bases of a vector space)
  - Tensor calculus (Einstein convention, Kronecker symbol, anti-symmetry symbol)
  - Notations for grouped multiplications (Big Sigma) and sums (Big Pi)
  - Axioms for set of real number
  - Definition of various Inequalities
  - Circular and related movements
  - Inertial forces (Coriolis force)
  - Drake Equation

- **August 12002**
  - New biographies (Hilbert, Riemann, Legendre)
  - New section "Humor"
  - Introduction to Topology
  - Euclid postulates
  - Gauss plane (complex numbers)
  - De Moivre’s formula
  - Transformations in the complex plane
  - Base change and tensor scalar product
  - Covariant and contravariant components
  - Relativistic transformations of the momentum
  - Prefixes of multiples and submultiples of SI units
  - Quality control (probabilities), efficiency curve, level value of acceptable quality (LQA)
  - Kepler’s laws
  - Proof of classical gravitational force from Kepler’s Law
  - Proof of area law (second Kepler’s Law)
  - Moment of force
  - Angular momentum
  - Theorem of angular momentum
  - Newton-Poisson Equation
  - Thomson’s, Bohr’s and Sommerfeld-Bohr’s atom model
  - Hydrogen spectrum
  - Assumption of Neutron
  - Quantum numbers
  - Pauli exclusion Principles
  - Classical Analysis of the Schrödinger equation for the ideal rectangular potential
  - Newton’s Laws
  - Proof of Newton’s third law from the principle of least action
  - Release speed (for rockets or others)
  - Definition of "Scientism"
  - Variation of the gravitational acceleration in and out of a homogeneous spherical body
  - The principle of least action and quantum physics (semi-classical limit)
  - Ballistics (maximum range, safety parabola)
  - Introduction to nuclear physics
  - Atomic number, mass number
  - Radioactivity, activity, decay chain, isotopes, isotones, nuclide dating
  - Atomic mass system (UMA)
  - Mass defaults
  - Fusion and fission
  - Alpha and beta (minus and plus) disintegration
  - Electron capture
  - Gamma emission

- **September 12002**
  - New Biographies (Dalton, Boltzmann, De Broglie, etc.)
  - Principle of good order
  - Archimedean Property
  - Induction Principle
  - Divisibility (Euclidean division)
  - Congruent numbers
  - Proof by nine
  - Numbers basis
  - Definition utility of thousands separators
  - Priorities of parenthesis, brackets, braces and arithmetic operators
  - Proof Theory (introduction)
  - Definition of terms, formulas and demonstrations
  - Definition of languages, symbols, relations and functions
  - Definition of periodic, compound, basic, rational, fractional, irrational, algebraic and transcendental numbers
  - Generalization of elementary algebra
  - Dimensions of a vector space, extension of a free family, rank of a finite family
  - Vector Hyperplane, direct sums
  - Almost rigorous definition of the concepts of line, surface (plane) and volume
  - Straight line intersection, half-lines, segments, aliquot part
  - Continuity axiom of the line and of the plane
  - Translation and rotation of plan
  - Angles, units, measurements, sides of the angle, sharp edges, flat angles, equal angles ,straight angles, acute angles, obtuse angles, supplementary angles, complementary angles,
  - Perpendicular lines, bisecting angle
  - Definition of work and energy: kinetic and potential energy theorem (motor work and resisting work)
  - Concept of conservative vector field
  - Conservation of energy and momentum
  - Mass center theorem
  - Relativistic force transformation
  - Relativistic transformations of electric and magnetic fields
  - Chandrasekhar limit weights (collapse limit of white dwarfs)
  - Definitions of optics, generalization of the law of refraction
  - Broglie normalization condition, linked and non-linked states
  - Harmonic oscillator
  - Quantum chemistry and molecular vibrations
- **October 12002**
  - New biographies (Cauchy, Neumann, Bessel, Archimedes)
  - New section on "Theoretical Computing"
  - Greatest common divisor, least common multiple
  - Rule signs (...)
  - Proof of the irrationality of a number
  - Introduction to arithmetic, harmonic and geometric sequences

  - Limits and continuity of functions
  - Definition of affine spaces
  - Introduction to the Euclidean tensors and their properties
  - Triangles and properties of triangles
  - Definition of thermodynamic systems
  - Definition of the reduced mass
  - Bessel's functions
  - Definition of the moment of inertia
  - Introduction to Quantum Field Theory
  - Introduction to radiation protection
  - Proof of Bethe-Bloch formula
  - Tunnel effect in quantum physics
  - Introduction Dirac's formalism
  - Heron and Archimedes algorithm's
  - Introduction to fractal sets
  - Introduction to game theory (cooperative games, earnings, payoff matrix, extensive forms, Pareto optimums, Nash equilibrium, evolutionary games)

- **November 12002**

  - Fundamental theorem of arithmetic
  - Introduction to cryptography (RSA, DES, MD5, SHA-1)
  - Euler phi function
  - Small Fermat theorem
  - Introduction to topological dimensions and scaling
  - Cosine directors

- **December 12002**

  - New Biographies (Nash, Cartan, Lucas, Lie)
  - Detailed development of the "Integer" function
  - Superposition of linear quantum states (quantum coherence)
  - Definition of Lipschitz functions and contracting functions
  - Definition of a convergent Cauchy sequence
  - Fixed point theorem (used in fractals, Newton methods and many others)
  - Definitions of reality, the problem of the theory and trial on reality
  - Definition of Euclidean space and Euclidean affine space
  - Definition of property concepts in the field of chemistry

- **January 12003**

  - Pascal's Theorem
  - Buoyancy (Archimedes' principle)
  - Simple Introduction to different symmetries in physics (temporal, spatial)
  - Simple Introduction to different transformations in the plane (translation, scaling, reflection, isometry, rotation)
  - Definition of an inverse and composed function/application
  - Trigonometry (introduction, remarkable relations/identities, spherical trigonometry)
  - Signature of a vector space
  - Schmidt orthogonalization methods, base changes, Fourier associated spaces

  - Everything (almost) on the plane and spherical trigonometry
  - Keplerian orbital trajectories
  - Introduction to the neoclassical monetary model (Say/Walras laws, homogeneity assumption)
  - Boolean algebra (simple properties and theorems)
  - Redesigned of quantum physics section (order of the subjects)
  - Proof of evolutionary Schrödinger equation
  - Proof of the relativistic evolutionary Schrödinger equation
  - Introduction to Antimatter theory

- **February 12003**
  - Proof of gradient, divergence, rotational and Laplacian in cartesian, polary, cylindrical and spherical coordinates
  - Complete mathematical developments of speed and acceleration expressions in cartesian, polar, cylindrical and spherical coordinates
  - Proof of the relativistic invariance of the electric charge (charge conservation equation)
  - Proof of the existence of anti-particle with opposite charge
  - Introduction to Gauge Theory (quadripotentiel Lorenz gauge, Coulomb gauge, Alembertian)
  - Introduction to Lagrangian and Hamiltonian formalism (generalized coordinates, configuration spaces, Euler-Lagrange equation, canonical formalism, Legendre transformation, Poisson brackets)
  - Rigorous definition of the principle of least action
  - Definition of Tensor spaces

- **March 12003**
  - New Biographies (Lorentz, Minkowski Hermann, Ricci-Curbastro, Levi-Civita)
  - Definition of Cartesian product and extension of the scope of application of Cardinals
  - Proof of Cauchy-Schwarz inequality
  - Proof of the triangle inequality
  - Definitions of the vector product and mixed product
  - Proof of condensed form the sum of the first n integers
  - Proof of the validity of the integration by parts
  - Definition of the algebraic vectorial structure and of an algebra
  - Definition of a homomorphism, isomorphism, endomorphism, automorphism

- **April 12003**
  - New Biographies (Göpper-Meyer, Yukawa, Nöther, Cournot)
  - Cournot Theory equilibrium (competition)
  - Wilson's model (inventory management)
  - Mathematics of phasers
  - Relativistic model of the Sommerfeld's atom
  - Analytical resolution of the Schrödinger equation
  - Heisenberg's principles of quantum uncertainty
  - Lagrangian formalism of quantum physics fields

  - Improvement of website forum (add mathematical symbols and external files)
  - 10 new links to interesting web pages (associations + math stuff)

- **May 12003**
  - New Biographies (Bell, Ramanujan, Landau)
  - Proof of the precession of the perihelion of coupled orbits of stars or electric charges
  - Definition and developments related to the Virial theorem
  - Calculation of potential energy of a material sphere (internal temperature of Stars)
  - Definition of prime numbers and proof that they are in infinite in number
  - Definition of a fully enclosed ring
  - Proof that a rational number is an algebraic number if and only if it is a relative integer.
  - Definition of a multi-linear application/function (or morphism of vector space)
  - Definition of a partition of a set and an equivalence class.
  - Descriptions of set operations of absorption and idempotence.
  - Definitions and examples of sagittals diagrams.
  - Definition of a magma and a monoid
  - Pseudo-proofs of algebraic structures of fundamental sets of arithmetic
  - Development of the theory of angular momentum in wave quantum physics
  - Definition of a Diophantine equation and sets of Fermat's Last Theorem

- **October 12003**
  - New Biographies (Abel, Banach, Boole, Bose, Brouwer, Clausius, Cayley, Curie, Connes, Dirichlet, Frege, Gibbs, Picard, Erdos, Grothendieck, Hamilton, Hausdorf, Heaviside, Helmholtz, Hermite, Hoyle, Jacobi, Klein, Kronecker, Langevin, Lee, Lobachevsky , Möbius, Monge, Fish, Schwartz, Shannon, Thom, van der Waals, Vieta, Weinberg, Witten, Gamow, Sturm, Liouville,Clairaut, Teller)
  - Definition of punctual spaces in classical mechanics, of writing conventions and changes in referential
  - Mathematical theory of projective perspective with vanishing points and definition of the projective and isometric perspectives
  - Simplistic definition of the concept of "derivative" in functional analysis.
  - Proof of some common derivatives (polynomials, composite functions, inverse functions, cosine, sine, arc sine, arc cosine, quotient of two functions, etc.).
  - Numerical Methods: mathematical explanation of the complexity of an algorithm and elementary optimization research
  - Method of calculating the number e
  - Resolution Method of n linear equations systems with n unknown using the pivot method
  - Search of function roots by the methods of the proportional parts, of the bisection method, of the secant methods (regula falsi) and Newton's method
  - Calculations of areas and integrals using the Riemann sums method
  - Presentation of the Monte Carlo calculation for integrals, or Pi
  - Mathematical development of simplex algorithm used in the operations research (linear programming)
  - Contraction of indices in tensor calculus
  - Definition and detailed properties of some special tensor (symmetric tensor, anti-symmetric tensor, fundamental tensor, etc.)

  - Curvilinear coordinates (determination of the metric and linear element of a spherical and cartesian space and of the plane in polar coordinates) Christoffel symbols (first and second type).
  - Proof of the Cantor-Bernstein theorem
  - Determination of the free generalized Lagrangian in General Relativity

- **December 12003**
  - New Biographies (Kirchhoff biographers, Markowitz, Cox Merton, Scholes, Sharpe, Ferdinan von Lindemann, Bachelier, Stefan)
  - Proof of one of the Stirling formulas
  - Detailed calculation of a simple model of a Star surface temperature
  - Detailed calculations of temporal properties of the securities values
  - Proof of Taylor series and Maclaurin (limited and unlimited)
  - Defining the Lagrange rest and of Alembert's, Cauchy, integral test and absolute convergence criteria
  - Developments relative to the definitions of brightness, luminosity, apparent and absolute magnitude of Stars and calculation of the distance to Cepheids
  - Definitions of the solid angle, the solid angle of revolution and the elementary solid angle
  - Definition of photometric and photonic and international system quantities
  - Definitions and developments related to the light intensity, energy flow (with proof of Beer-Lambert' law), emittance, radiance (with Lambert's law), Kirchhoff's law
  - Proofs of Stefan's law and Stefan-Boltzmann law
  - Resolutions of third degree polynomials by radicals (Cardan's method) and development about solving quadratic polynomials in the complex set
  - Definition of the concept of equations and inequalities
  - Determination of the Cartesian equation of the plane, line (in space),cone and sphere
  - Definition of market efficiency
  - Determination of the Black & Scholes equation
  - Presentation of the mathematical aspects of Wiener process
  - Ito lemma and Brownian motion (random walk)

- **January 12004**
  - Definition of the indefinite integral
  - Newtonian cosmological model (without the cosmological constant)
  - Statement of the Peano's
  - Introduction to Linear Algebra (Gauss reduction method, elementary operations between matrices)
  - Statement of 5 Euclid's axioms and 5 groups of axioms in geometry
  - Proof of relations for calculating the perimeter of the surface and the center of gravity of the square, the rectangle and triangle
  - Proof of relations for calculating the volumes and surfaces of the torus, the sphere, the ellipsoid, cylinder and cone
  - Definition of the centroid (center of gravity) and demonstration of four properties related thereto
  - Demonstration of decomposition odd function and pair of any function
  - Definition of hyperbolic trigonometric functions and enumeration of relations and proof of related remarkable properties

  - Introduction to differential geometry (definition of a Riemannian geometry, Frenet triad, parametrised surface, etc.)
  - Introduction to graph theory (Königsberg's bridges proof)
  - Definition of a topological space and Hausdorff definition of a metric / ultra-metric space and associated distances (hölder, discreet, equivalent ...)
  - Definition of a Lipschitz function (and related isometrics)
  - Definition of open and closed set (open/closed balls, spheres, adherence, Hausdorff's excess) and diameters
  - Definition of set distances (gap) and of a variety / map / atlas and differential homeomorphism

- **April 12004**
  - Proof of the Guldin's theorem
  - Proof of König's theorem of kinetic energy and angular momentum
  - Presentation and proofs of various techniques for calculating the moments of inertia: Huygens-Steiner theorem, polar inertia moment, inertia tensor, generalized Huygens-Steiner
  - Definition of "power" and "performance" and proof of the calculation of the power of a rotating machine
  - Proof of Boltzmann thermodynamic entropy law and the following statistical distributions: Maxwell speeds, Maxwell-Boltzmann, Fermi-Dirac, Bose-Einstein
  - Proof of some principal moments of inertia of the following bodies: torus, spheres, cones, rectangular plate, tube
  - Introduction to wave optics: Huygens principle, proof of Malus law, development of Fraunhofer model in the case of a rectangular slot.
  - Definition and proof of the resolving power of a simple rectangular slot.
  - Proof of the origin and the solution of the no less famous Bessel differential equation of order n
  - Proof of the wave function of a stretched rope and a stretched circular membrane
  - Proof of Planck's law and of known approximations (first Wien's Law, Rayleigh-Jeans law).
  - Proof of the displacement law (second Wien's law) and the Stefan-Boltzmann law through Planck's law and determination of the Stefan-Boltzmann constant
  - Study of the origin of Planck dimensions: Planck length, Planck mass, Planck density, Planck time, Planck energy

- **July 12004**
  - Proof of the physical origin of heat
  - Proof of Torricelli's theorem
  - Proof of Venturi effect
  - Proof of Poiseuille's law
  - Proof of relativistic Compton effect
  - Proof of the existence of the fossil radiation in the Universe
  - Introductions to quotients sets (in this case $\mathbb{Z}/n$
  - Proof of the physical origin of heat
  - Proof of Torricelli's theorem
  - Proof of Venturi's effect
  - Proof of Poiseuille's law

  - Proof of relativistic Compton effect
  - Proof of the existence of the fossil radiation in the Universe
  - Introductions to quotients sets (in this case $\mathbb{Z}/nZ$)
  - Proof of Lorentz transformations for speed and acceleration
  - Determination of the relativistic Lagrangian of a free system
  - Proof and definition of Ricci theorem, of the covariant derivative, of the Ricci identity, of the Riemann-Christoffel tensor, of the Ricci tensor, of the Ricci scalar, identities of both Bianchi and finally Einstein tensor
  - Mathematical definition of the capacity and determination of the expression of a parallel plane capacity
  - Determination of the electrostatic potential energy
  - Proof of the value of the field of and electric potential of a straight infinite wire.
  - Determination of the basic properties of electric dipoles as the rigid dipole moment, the presentation of the induced dipole moment, hydrogen bonds, Van der Waals forces, etc.
  - Definition of the Curie symmetry principle and Statement of 6 resulting properties
  - Definition of pseudo vectors
  - Proof of the relations for the volume of the pyramid, the paraboloid, the tetrahedron, octahedron, cube and parallelepiped
  - Determination of the magnetic field produced by a toroidal solenoid, a rectilinear solenoid infinity and a current loop
  - Determination of the magnetic field produced by a magnetic dipole and basic definitions of the properties of magnetic materials
  - Calculation of the Armorial radius and cyclotron pulsation in a non-relativistic framework
  - Determination of the Lagrangian of the electromagnetic field and by extension in the non-relativistic approximation of the tensor of the electromagnetic field
  - Introduction to the calculation of the radiation emitted by an accelerated charge (synchrotron radiation, Lienard-Wiechert's retarded potentials)
  - Calculation of the values of resistors and capacitors in series
  - Difference between electrical potential and electromotive potential
  - Proof of Faraday's law and definition of "self inductance"
  - Proof of Descartes formulas for the concave and convex spherical surfaces and refracting/not refracting as well as for refractive lenses.
  - Definition of stigma and proof that the parable is strictly stigmatic
  - Proof of Descartes formulas for thin lenses and conjugation law
  - Definition of diopter and explanation of various visual disabilities

- **September 12004**
  - Statement of Mach's principle
  - Presentation of the photoelectric effect and proof of the physical law governing it.
  - Proof by example that the light can be seen as both a particle or as a wave
  - Proof of the theorem of monotone class
  - Detailed proof of generalized Klein-Gordon equation (relativistic particle in a magnetic field)
  - Detailed proof of free Dirac equation with explicit Paulis solutions (particles, antiparticles)
  - Determination of the radius of the atom using the Rutherford-Coulomb scatter-

  ing(verbatim: determining the cross section for Rutherford)
  - Presentation of macroscopic and microscopic interactions of X and gamma-rays with matter (which includes details study of the materialization of a photon in electron-positron pair)
  - Introduction to spinors
  - Definition of operating properties of matrices, remarkable matrices, determinants, eigenvectors and eigenvalues
  - Statements of the postulates of wave quantum physics
  - Determination of the orbitals of the hydrogen-atom

- **November 12004**
  - New Biographies (Smith, Say, Malthus, Keynes, Walras, Pareto)
  - Presentation and proof of Noether's theorem
  - Enumeration of some major physical chemical, astronomical constants
  - Introduction to the theory of speculation: (predictive expectation of a financial asset)
  - Introduction to the preference theory (Arrow-Debreu model)
  - Presentation of solutions of the Black & Scholes equation and remarks on the delta - Proof of the Call-Put parity equation
  - Determination of initial stock (optimum) within the framework of the supply chain management

- **January 12005**
  - New Biographies (Penrose, Hawking, Turing, Marx)
  - Development of "dual" version of Maxwell equations and proof of the origin of the expression (hypothesis) of magnetic monopoles
  - Definition of P, NP and NPC class algorithms
  - Proof of the fundamental theorem of calculus also named "fundamental theorem of integral and differential calculus"
  - Presentation of the cGH cube and the Copenhagen interpretation
  - Introduction to the mathematical concepts of artificial neural networks
  - Introduction to the mathematical concepts of Genetic Algorithms
  - Detailed mathematical introduction to fractals
  - Basics maths stuffs on Quantum Computing
  - Introduction to fuzzy logic
  - Proof of Shannon theorem, Morgan theorems, expansion theorem, Karnaugh maps, complete adder, full subtracter

- **April 12005**
  - Basic definitions on block codes, linear codes, systematic codes in error correcting codes
  - Proof of the relation of the relativistic change in mass
  - Introduction to codes and prefix codes
  - Proof of the formula for the calculation of the number of days between two given dates
  - Rounding calculations techniques
  - Definition of rigid or non-rigid post and praenumerando annuities with or without constant rate (certain future)

  - Definition and study of the properties of loans repayment or constant annuity

- **April 12006**
  - Presentation of Schild's criterion via the Einstein effect (gravitational redshift)
  - Development of the Newtonian approximation of the geodesic equation
  - Definitions and proofs of developed forms of four-vectors of displacement, velocity, current, acceleration and energy-momentum
  - Proof of the provenance of electromagnetic field tensor and referential calculation changes
  - Definition of a tautology and principle of non-tautology
  - Descriptions, definitions and many proofs on quaternions
  - Proof of Euler's number irrationality
  - Definition of the log-normal, triangular and Weibull distribution and proof of their mean and standard deviation
  - Introduction to error calculation (absolute and relative uncertainties, error propagation, significant numbers, etc.)
  - Proof of the deflection of light near a Star with the Newtonian gravitational model
  - Definition of a rotation matrix (and developments related thereto)
  - Proof of the existence of the Euclidean division in the ring of polynomials
  - Definitions of MWRR (Time of Money Weighted Return) and TWRR (Time Weighted Rate of Return)
  - Proof of Gauss-Ostrogradsky theorem

- **July 12006**
  - Definition of the concept of dual space
  - Definition of Pareto law and proof of mean and standard deviation
  - Definition of quantile (quartile, percentile)
  - Proof that the mode is the value that minimizes the absolute dispersion
  - Proof of Minkowski and Bienaymé-Tchebychev inequalities
  - Proof of the weak law of large numbers
  - Proof of Euler's formula for planar graphs
  - Introduction to the mathematical method of Six Sigma process controls
  - Proof of the variational calculus theorem
  - Proof of the calculation of the apparent superluminal speed of a high Redshift Star
  - Zero-sum game resolution method using operational research
  - Definition of investment funds
  - Proof of the beta expression of a simple linear regression model (Sharpe)

- **October 12006**
  - Proof Binomial and Poisson likelihood estimators
  - Presentation of the concept of "color" and subtractive and additive synthesis
  - Proof of Einstein equation fields (approach using weak fields approximation)
  - Differentiation of the equivalence principle, weak equivalence principle and Einstein's equivalence principle
  - Proof of the duration of the Daytime arc of planets in the approximation of the null precession and nutation
  - Digital and formal study (approximative) of Lagrange points of a binary system

  - Method of resolution of 4^{th} degree polynomial (Ferrari's method)
  - Presentation of the Gram determinant via the Euclidean volume represented by the joint product of the vectors of a canonical basis
  - Definition of monotonic, strictly monotone functions, etc .. without pure formal approach
  - Approximative determination via the Yukawa potential (mass fields) of the mass of mesons of the weak interaction and the strong nuclear interaction.
  - Introduction to first order linear differential equations

- **December 12007**

  - New Biographies (Heckman, McFadden, Tesla)
  - Bernoulli numbers and polynomials
  - Roche Limit
  - Flattening of celestial bodies
  - Pressure and kinetic temperature
  - Proof of a special case of magnet or electromagnet force
  - Fundamental introduction to Hermitian and Hilbert vector spaces
  - Schwarzschild solution in General Relativity
  - Precession of the perihelion of Mercury in General Relativity
  - Light Deflection in General Relativity
  - Shapiro delay in General Relativity
  - Evaluation Model of Financial Assets
  - The Black Hole Universe
  - Coupling constants of fundamental interactions
  - Hamiltonian of the Schrödinger equation for a charged particle in an electromagnetic field
  - Markov chains
  - Theory of queues
  - Introduction to weather and marine engineering mathematics
  - Practical example in Microsoft® Excel® of the efficiency Markowitz model
  - Practical example in Microsoft® Excel® of the Sharp efficiency model
  - Simplified proof of Green(-Riemann)'s and Stokes theorem
  - Detailed proofs on principal component analysis (PCA)
  - Proof of the spectral theorem in the real numbers case
  - Detailed proofs on logistic regression
  - Proof of Rolle's theorem and mean value
  - Proof of the Hopital theorem and generalized finite increments (generalized mean value)
  - Introduction of Geometric law and proof of its variance and mean
  - Proof of calculation of the area and volume of the five regular Platonic polyhedra
  - Introduction to field algebra and geometry
  - Detailed calculations of the collapsing critical mass (Jeans' Mass) and critical radius (Jeans' Radius) of an interstellar cloud or stellar nurseries
  - Detailed calculations of the collapse time of an interstellar cloud
  - Detailed calculations of a Star nuclear life
  - Detailed mathematical introduction to Fourier transforms
  - Detailed resolution of homogeneous linear differential equations with constant coefficients

  - Presentation of the Cornu's spiral for civil engineering
  - Mathematics of biometric functions
  - Determination and simple resolution of the Pauli equation
  - General solution (Fourier transform) of the electromagnetic wave equation
  - Introduction to strength of materials
  - Visual Horizon
  - Growth rate of a population depending on the temperature
  - Pitot Tube and Pressure drop
  - $U(1)$ gauge theories in quantum field physics
  - Bezier curves
  - Differential equation system with matrix exponentiation

- **September 12009**
  - New Biographies (Pearson, Gosset, Fisher)
  - New important usual primitives for civil engineering and analytical mechanics
  - Detailed proofs of the origin of arcsinh and arccosh functions
  - Proof of Laplace equation and Mayer relation
  - Proof of the propagation of pressure waves
  - Historical introduction for nuclear physics
  - Proof of Maxwell relations in thermodynamics and introduction to free energy and enthalpy
  - Adiabatic atmosphere model
  - Proof of Lorenz equations and the butterfly effect
  - Calculations of some optical properties of the prism
  - Conditions of decoherence/interferences of electromagnetic waves
  - Bloch Sphere
  - Proof of the minimum surface of revolution volume
  - Treatment of the free particle
  - Treatment of the polarized spin qubit and the qubit of spin 1/2
  - Characteristic function and central limit theorem
  - Some proofs on the inequalities in triangles
  - Proof of the volume of a barrel with circular section
  - Proof of the origin of the mean and standard deviation to the Student and Fisher-Snedecor laws
  - Introduction to the marginal cost
  - Statistical test of the one-way ANOVA
  - Statistical Pearson's Chi-square adjustment test
  - Introduction to the analysis of variance of regression
  - Correspondence Factor Analysis
  - Development of linear free or forced RC, RL, RLC circuits

- **September 12008**
  - Simple or complex topology systems analysis for preventive maintenance
  - Introduction to finite and infinite continued fractions
  - Detailed Solutions of a rectangular tunnelling barrier
  - Mathematical model of alpha decay via tunnelling
  - Introduction to Brownian motion model according to Langevin model
  - Introduction to tribology/friction

  - Introduction to time series analysis
  - Additional proofs on long term and short term process capability indices and measuring devices in Statistical Process
  - Proof of the calculation of the PPM in SPC centered or non-centered process
  - Proof of Taguchi quality cost relation
  - Proof of Lienard-Wiechert expression of electric and magnetic potentials
  - Introduction to complex analysis
  - Proof of the second Friedmann equation in cosmology
  - Proof of "slowing" of light near a Black Hole
  - Proof of the expression of the Taylor expansion of a function of two real variables
  - Introduction to experimental design (DoE)
  - Proof of Eherenfest's theorem
  - Proof of the likelihood estimators of the Weibull distribution with two parameters
  - Example of application of decision theory
  - Bands theory (parabolic and semi-classical approximation) within semiconductors
  - Theorem of residues and Laurent series
  - Proofs of Lean Six Sigma values for business processes/workflows

- **October 12011**

  - New Biography (Erlang, Hotelling)
  - Detailed calculation of the geostationary orbit
  - Calculations on PVC meteorological probe balloons
  - Developments on the symmetrical gyroscope and weighing router
  - Detail calculations and proof on Gini index
  - Secular balance, transient and non-equilibrium in radioactive filiation
  - Detailed calculations on the approximate radius of rapidly rotating Stars
  - Proofs on historical delta-normal and variance-covariance Value At Risk
  - Two new jokes in the Humor section
  - Empirical statistical model of wage control
  - Simplified proof of the possible absence of arbitrage opportunity in Finance
  - Calculations on self-financing portfolio on the underlying risk
  - Introduction to mathematical techniques in Insurance
  - Mathematical developments on the power and intensity of a longitudinal sound wave
  - Statistical bilateral Z-test on the difference in the two means
  - Statistical Student T-test on two paired sample means
  - Proof of statistical confidence interval relation of sample large proportions
  - Statistical test for equal proportions of two large samples
  - Application of Shannon's theorem to calculate a statistical index of diversity
  - Proof of the determination of coefficients of a multiple linear regression
  - Proof of the determination of the coefficients of a simple linear regression through the origin
  - Introduction to sensitivity analysis
  - Introduction and some proof on rank/order statistics
  - Demonstration of the provenance, hope and variance of the negative binomial distribution
  - Control charts with detailed mathematical proofs
  - Mathematical approach of first Google Page Rank algorithm
  - Proof of Beltrami's identity to simplify the Euler-Lagrange equation

  - Exact binomial statistical test for the balance of a population with two characteristics
  - Developments and study of gravity waves in a fluid
  - Some simple developments on the gears/gear shafts
  - Proof of skin's effect
  - Theory of the rainbow
  - Theory of double pendulum
  - Boltzmann distribution law
  - Dalton's and Amagat laws
  - Heat Flow
  - Average power in alternative current
  - Presentation of some detailed calculations on the betatron

- **May 12013**

  - New Biographies (Napier, Wilcoxon, Born, Heisenberg, Jordan, Kolmogorov, Stokes, Ostrogradsky, Zeeman, Joseph, Faraday, Meitner, Curie, Biot, Debye, Drude, Ohm)
  - Detailed example of construction of a particular neural network with Microsoft® Excel®
  - Resolution of homogeneous linear differential equations of order 1 with non constant coefficients
  - Example of a Fourier transform of a Gaussian function and proof of the property of the Fourier transform of a derivative
  - Introduction to interactions in two-factor ANOVA
  - Confidence interval and prediction interval of a linear regression
  - Statistical Test signs (median test)
  - Introduction of conditional probability and the conditional mean of Pareto law
  - Determination of the estimators of the gamma distribution using the method of moments
  - Second mathematical approach to the identification of the tides
  - Statistical Kolmogorov-Smirnov adjustment test with Lilliefors approach
  - Proof of the Scheafer's quota model
  - Proof of the calculation of the synodical period of the planets and of demotion of time
  - Proof of the construction of Brownian bridges
  - Proof of the origin of the rare events control chart
  - Calculation of the discount factor of a retiring insurance based on inflation and life expectancy
  - Proof of two-factor ANOVA relations without repetition and repetition
  - Mathematical proof and physics of the LASER
  - Theorem of Taylor series with integral rest
  - Stability of the Poisson distribution
  - Statistical Poisson test for 1 or 2 samples
  - Statistical non-parametric Kruskal-Wallis and Friedman tests
  - Statistical normality test of Ryan-Joiner
  - Statistical C Cochran test
  - Usual Taylor-Maclaurin Series
  - Polynomial regression by least squares method
  - Spatiotemporal Finite Difference Method with Maxwell's equations

  - Break-even Analysis
  - Mechanical Harmonic Oscillator
  - Acoustic Doppler Effect
  - Periodic waves overlays
  - Statistical Tukey test of range
  - Forecasting models by moving average, seasonal coefficients, simple smoothing, Brown double smoothing, double Holt (additive) smoothing, double Holt and Winter (multiplicative) smoothing
  - Introduction to elementary AR, AM, ARMA and ARIMA autoregressive models
  - Proof of the expression of the correction factor on finite population
  - Statistical Fisher exact test
  - Exponential Laplace Smoothing
  - Cohen approval Kappa and McNemar statistical test
  - Kaplan-Meier survival analysis model
  - Cramer's V
  - Clustering K-Means algorithm
  - Clustering Dendrograms algorithm
  - Statistical Wilcoxon signed rank test for one sample or two paired samples
  - Quantitative study of the effective potential energy (harmonic model of the atomic bonding) of the hydrogen-atom
  - Proof of beams equation (Euler-Bernoulli equation)
  - Calculation of the failure rate of a system using the technique of maximum likelihood
  - We added a chronology of Sciences
  - Proof of Einstein model (Dulong-Petit law) of the heat capacity of crystalline solids and derivation of the Debye model
  - Langenvin Model of diamagnetism and paramagnetism
  - Introduction to line integrals calculation
  - Naive determination of the energy of a magnetic dipole
  - "Liquid drop" nuclear Model
  - Magnetic model of spin resonance
  - Integrating factor method for solving differential equations
  - Constant variation method for solving differential equations
  - Mendel's law
  - Temporary and Deferred Life Annuity
  - Carnot Cycle
  - Durand and Gordon-Shapiro equity valuation model
  - Statistical Anderson-Darling adequation test
  - Non-linear optimization by the Newton-Quadratic and Gauss-Newton methods
  - Lagrange Polynomial interpolation method
  - Statistical Cochran-Mantel Heanzel test

- **November 12016**

  - Singular value decomposition theorem

- **December 12016**

  - Fieller's test (ratio of two means)

- **January 12017**
  - Falling Chimney problem
  - Levey-Jennings control charts
  - Simple lattice mixture design of experiment with process variables
  - Average Failure Rate (reliability)
  - Markov Chain Reliability Model
  - Design of reliability tests (Chi-squared time of test, Binomial sampling size, Beta-binomial sampling size)
  - Weibull distribution linearisation
  - Inverted pendulum
  - Durbin-Watson autocorrelation test
  - Fisher's method for multiple p-values
  - Magnifying glass
  - Laney's control chart
  - Classification of conical by the determinant
  - Classification of partial differential equations
- **February 12017**
  - Folded Normal distribution basics CDF and PDF
  - Half-Normal distribution CDF, PDF, variance, mean and median
  - Telescopic and Gandi's series
  - Césaro's sum
  - Implicit Differentiation
  - Bivariate chain rule
- **March 12017**
  - Laplace Integration method
  - Lenth's PSE Pareto Margin Error for unreplicated factorial designs
  - Pareto Margin Error for replicated factorial designs
  - Design of Experiments desirability
- **April 12017**
  - Friedmann–Lemaître–Robertson–Walker metric
  - Jensen inequality
- **May 12017**
  - Introducing weak field gravitational waves equation
  - A mathematical approach of "Divide and rule?" in management
  - Three new jokes in the Humor section
- **July 12017** (v3.7 → v3.8)
  - Correction of many typing errors (almost 50)
  - Relation 11.3.221 had a integral symbol (that should not be there)
  - Relation 7.1.72 had a wrong variable for the angle
  - Relation 7.5.56 there was a $|a|$ instead of a $|b|$ in the second equality
  - Relation 11.1.35 had a 4 that has nothing to do there at the numerator

  - Relation 15.7.905 there was an alignment issue
  - Relation 15.7.888 had a Λ instead of a Γ at the denominator
  - Relation 11.1.20 had a missing T
  - Relations 11.3.169 must be r_E instead of $r-E$ (LaTeX typing error...)
  - Table 8.10 and 8.11 had wrong units in the header row
  - New photo about a quasi vertical circular rainbow and a photo a nuclear magnetic resonance machine
  - There was a typing error in the period (T) relation of the simple pendulum
  - Details of the back-propagation method for neural network
  - New mathematical details on the simple linear regression leverage
  - Numerical applications of some General Relativity experimental tests
  - Derivation of the geodesic of the sphere (as example in the section of Analytical Mechanics)
  - ZeroR classification method
  - K nearest neighbours classification method
  - Definition of Convexity/Concavity of a function (for Jensen inequality proof)
  - Proof of Hermite polynomial Orthogonality
  - Derivation of the Bachelier Option Pricing Model
  - Derivation Forward/Future Cox-Ross-Ingersoll Equality
  - Derivation of the Stress-Energy tensor for a non-relativistic perfect fluid
  - Derivation of the orthodromic distance
  - Derivation of the area of a section of an ellipse
  - There was twice a "Invariance by translation in space" Noether theorem... one of them was obviously "Invariance by translation in time"
  - Schwarzschild innermost stable orbit
  - Hafele–Keating experiment with General Relativity treatment
  - Introducing hyperparameters in Machine Learning
  - Kernel smoothing
  - Credit Default risk
  - We added a lot of new entries in the Chronology section

- **November 12017** (v3.8 $\rightarrow$ v3.9)

  - Section numbering was not correct anymore because of a MiKTeX update.
  - We created all simple cross references
  - Multiple errors in PPI (proton-proton Sun chain function reaction) in relations 11.2.27, 11.2.29 and 11.2.30
  - We added one point to the scientific publication rules (cite equivalent studies for meta-analysis)
  - Correction of a few hundred minor typing errors
  - Typing error in the relation 5.4.231, the first line should be a $\cos(x)$ and not a $\sin(x)$
  - Read "multiplication" instead of "addition" in the remark below the relation 4.2.164.
  - A square was missing on the 2 in 4.4.13.
  - A square was missing on the r in 12.1.57
  - There was a "$+$" instead of a $\cdot$ in 10.2.21
  - Square was missing in relation 4.7.1479, 4.7.1480, 4.7.1481, 4.7.1482. 4.7.1484
  - There was a c^3 instead of a c^2 in the relation 11.1.212
  - At 8.3.450 three paragraphs and two equations were duplicates
  - Proof of the derivative of $f(g)^{g(x)}$

  - OneR (One Rule) in Data Mining with confusion matrix rule selection
  - Apriori Association Rule
  - Kurtosis and Skewness

- **January 12018** (v3.9 → v3.10)
  - Typing error in relation 8.2.160 (a ∂ missing)
  - Typing error in relation 9.3.305 (a μ was missing)
  - There was an error sign in all inverse Fourier transform (error made during the translation of the book into English).
  - Dirac continuity equation
  - CCR (Charnes, Cooper and Rhodes) model of Data Envelopment Analysis (DEA)
  - Kullback-Leibler divergence
  - Continuous and Discrete Linear Convolution
  - Dirichlet Integral
  - Permutation tests
  - Binomial and Gaussian naive bayes
  - More cross-references added

- **June 12018** (v3.10 → v3.11)
  - Typing error for the return angle range of the function $\text{atan}()$ ($-$ instead of a $+$)
  - There was a typing error in relations 4.7.264 and 4.7.265 (power of 3 instead of 2).
  - There was a typing error in relation 4.7.512 a $\text{E}(X)$ instead of a $\text{V}(X)$.
  - A c was missing in relation 4.5.125
  - There were typing error in relations 13.1.739 and 13.1.740
  - A q was missing in relations 9.1.31 and 9.1.32
  - A N was missing in the third relation 14.4.238
  - We added a few more Taguchi tables and Taguchi interaction tables
  - We added the derivation of the one degree of freedom non-central chi-square distribution for the study of tolerance intervals
  - We added new details about the regression forced through the original (especially on the problem of the R^2 calculation)
  - We added some new images (on data fallacies, a joke with Schrödinger cat, planet's comparison size with respected proportions, an illustration of the difference between bagging and boosting)
  - We added in the section of Astronomy data tables with the major properties of interest of the planets of our solar system (including Pluto...)
  - We added in the section of Astrophysics a small data table with the major properties of some well known stars
  - Almost ten section headers were are at the wrong level in the table of contents (...)
  - Surprisingly some subjects on Neutron Stars had disappeared (don't ask why...!?). We put them again.
  - Cox Survival Model (Cox Proportional Hazard Model)
  - We made more explicit the link between the Gauss-Newton method and the gradient descent method
  - We added the confidence interval for the Kaplan-Meier estimator and Cox proportional hazard model (i.e. hazard ratio)

- **December 12023** (v3.11 → v4.0)
  - We noticed that a whole section on Lenz law and inductance wasn't translated since the version 3.1...
  - Typing error in the equality in the sentence below equation 14.4.125
  - Translation error in the axiomatic system of Lukasiewicz (the first line had a "Axiom A5" instead of "Axiom A4")
  - The symbol used for the AND connector in the table 4.5 and the paragraph text were wrong (bad copy paste...)
  - Wrong copy/paste in relations 13.1.387 and 13.1.388 (the sum symbol and the index i should not have been there)
  - There was copy/paste error in the relation 7.7.247 (a d at the beginning that should not have been there)
  - There were some sign errors in the relations 7.1.20
  - Two terms were missing in the relation 4.7.356
  - There were typing errors in relations 8.5.92, 8.5.94 and 8.5.95
  - There was a copy/paste error in the definition of the weighted average 4.7.39
  - There was a wrong 2 factor in the definition of the covariance 4.7.157
  - We replaced all the $x^{'}$ and $x^{''}$ by x' and x''
  - There was a typing error for the energy stored in a capacitor
  - There was a typing error in table 5.11 for the tautology ($P \vee \neg Q$ instead of $P \vee \neg P$). Thanks to Matvii Hodovankiuk!
  - Improvements and corrections in the subsection relatively to the relativistic redshift
  - Improvements and corrections about the SVD theorem
  - We added a small biography of F. Yates, A. Friedmann, G. Lemaître, G. Cramer
  - We improved the FRLW cosmological models subsection
  - We added a few dozens more of spherical harmonics in the section of Quantum Chemistry (thanks to Wikipedia!)
  - We added a brief introduction to the concept of XYZ analysis
  - We introduced the concept of ideal mechanical advantage and actual mechanical advantage
  - Introducing LSTM and GRU recurrent neural networks
  - We corrected all the misspelling of "well know"...
  - Three new jokes in the "Humour" section
  - Mallows's C_p and Akaike Information Criterion (AIC) derivation
  - LASSO, Ridge and Elastic Net regularize regressions
  - Cross-over methods including the proof of the CV and GCV
  - Derivation of multinomial mean and variance
  - Weighted linear regression and general ordinary least squares
  - LU, QR and Cholesky decomposition details
  - Gabriel's Horn finite volume and infinite surface solid of revolution
  - Derivation or Black Hole's photon-sphere radius
  - Risk Parity portfolio optimization
  - Law of total variance (iterated law of conditional variance)
  - Robust estimators, M-estimators and W-estimators
  - Hertzian dipole (antenna) in harmonic regime in far-field approximation
  - Newton-Cotes simple integration methods (Simpson's and Trapezoidal methods)
  - Runge-Kutta methods for solution to ordinary differential equations
  - Linear ordering isotonic regression

- We added the biography of Jerzy Neyman
- Fourier series generative art
- Rayleigh scattering
- Telegrapher equation
- Inductance of a coaxial cable
- Hotelling's T-square test
- Double mass harmonic oscillator
- Lawson Criterion for D-T
- Determinant of block triangular and diagonal matrices
- Woodburry matrix identity and Sherman-Morrison relation
- Factor Analysis
- Total Unduplicated Reach and Frequency Analysis (TURF)
- Equivalence CLAss Transformation (ECLAT)
- Welch Test with Welch-Satterhwaite equation
- Trimmed means T-test
- Expectation-Maximization algorithm
- Euler's Homogeneous Function Theorem
- Eurer-Maclaurin theorem
- Planck's 11912 zero point energy radiation law
- Heisenberg uncertainty principle zero point energy
- Bayes Factor
- Abraham-Lorentz formula
- Adjusted R-squared
- Saha ionization equation
- Cosmological Radiowave Background recombination temperature
- Casimir Effect
- Quantum Cosmology (FLWR Wheeler-Dewitt equation)
- Cochran–Armitage test for trend
- Generative Neural Networks (GAN)
- Point biserial correlation
- Sellmeier equation proof
- Torque of a current loop (DC motor)
- Fresnel circular aperture and circular obstacle diffraction
- Moments generating function and cumulants
- Variance stabilizing transformation
- Laguerre polynomials
- Radial solution or hydrogenoid atom
- Thin film interference
- Fresnel coefficients
- Brewster's angle
- Mollweide projection
- Variance-Bias tradeoff derivation
- Variance-bias tradeoff derivation for OLS
- Antithetic, Conditional, Stratified sampling and importance sample Monte Carlo variance reduction techniques
- Gauss-Markov theorem detailed derivation
- Eddington luminosity and temperature limit (spherical case)
- Logistic Kolmogorov-Smirnov statistic

  - Why gold may be yellow according to special relativity
  - Betz's law
  - Mirage equation
  - Gravitational (non-relativistic) effective potential
  - Gaussian Wavepacket
  - Discrete and continuous time Kelly criterion
  - Added the biography of Maclaurin
  - Density-Based Spatial Clustering of Applications with Noise (DBSCAN)
  - Proof of the pricing of a perpetual bond
  - Pressure of most vessels

- **February 12024** (v3.11 → v4.0)

  - Calculation of power received by Earth from Sun to explain the seasons
  - Error corrected in the section Optics where index of refractions n_1, n_2 were inverted
  - Proof of the law of reflection (only the proof of law of refraction was available)
  - Proof of why stars are not visible on most space photos and videos of standard cameras
  - Proof of the origin of the value above 40 billion light years for the radius of the universe
  - Error correction in the biography of Laplace that was using the picture of Langevin

- **March 12024** (v4.00 → v4.1)

  - Rotating bucket with Newtonian fluid problem
  - Isoperimetric plane theorem
  - Cantelli's inequality
  - Hermitian Cauchy-Schwarz inequality
  - Fourier uncertainty principle
  - Correction of two typewriting errors in the proof of Student's law corrected
  - Introducing intuitively the multivariate canonical Student distribution
  - Index of refraction rate of change with altitude
  - Friedmann-Lemaître Euclidean flat, spherical and hyperbolic spaces dominated by vacuum
  - Correction of the relations 5.6.226 and 5.6.227 that were completely wrong
  - Equivalent Monthly Installment (EMI)
  - Lewis Carrol Epstein interpretation
  - Historical Friedmann universes models

- **April 12024** (v4.00 → v4.1)

  - Correction of the cumulated continuous uniform function that was wrong
  - There was a typo in the expression of composition law of accelerations in the study of the Coriolis acceleration ($\vec{r}$ instead of $\vec{v}_r$)
  - There was a typo in the expression of the orbital speed (R^2 at the denominator instead of a R)
  - An relation was massing in the section of Weather Engineering is the part concerning the study of winds
  - In the section of Engineering false numerical values were given for the energy received by the Sun on Earth at apogee or perigee.

- **July 12024** (v4.1 → v4.2)
    - Calculations related to the properties of a typical Siphon
    - Physical derivation of the $22°$ sun halo (and moon) effect
    - Mathematical treatment of the distinction of Earth's curvature
    - Correction of some french to english wrong translations about the definition of angles
    - We changed the download URL for the book
    - We removed the email contact address from the footer
- **September 12024** (v4.2 → v4.3)
    - We added an example of the triangulation method
    - We corrected a missing coefficient in all the density lagrangians of General Relativity
    - We corrected a typing error in the value of the Absolute Temperature
    - There was twice the same mathematical constant if the table of mathematical constants
    - On reader request we added the proof of $0.9999\ldots=1$
    - We added the Al-Biruni method for determining the Earth's radius
    - We added an example for the Cantor-Bernstein theorem
    - A square was missing (typing error) in a remarkable trigonometric identity involving the tangent
    - Lagrange inversion theorem proof (by Laplace method)
    - Diurnal temperature range
    - Spherical angular theorem
    - Relativistic apparent angle rotation (Lampa-Terrell-Penrose effect)
- **Mai 12025** (v4.2 → v4.3)
    - We added the explanation and physical derivation of Cavendish experiment for G
    - Derivation of Hill sphere (sphere of influence) in the circular orbit approximation
    - Derivation of the Equation of Time and the analemma
    - Derivation of the Borde-Guth-Vilenkin Theorem (BGV theorem) in FWLR metric
    - Proof of the second Borel-Cantelli lemma
    - Proof of the second Borel-Cantelli lemma
    - Proof of the equivalence of Wald Z-test for proportion and binary logistic regression Rao score test
    - Proof of the four-parts formula in spherical trigonometry
    - Introduction to tit for tat in game theory
    - Mathematics of sundials
- **June 12025** (v4.3 → v4.4)
    - Black Hole Flamm's paraboloid representation
- **October 12025** (v4.4 → v4.5)
    - We remapped the links to all various companions PDFs
    - Proof of the Generalized Ehrenfest theorem
    - Proof of the Time-Energy uncertainty principle

  - Definition of "scientific law"
  - Ballistic accounting Earth’s curvature
  - Field of View (FOV)
  - Introduction of the set of divisors
  - Basic calculation of saros cycles
  - Some typing errors corrections (a few dozens)

- **June 12026** (v4.5 → v4.6)
  - Derivation of the expression of flatness of a rotating celestial body
  - Eötvös effect

- **December 12026** (v4.6 → v4.7)
  - Derivation of Euler rotation equation
  - Morse potential
  - Derivation of the surface of a spherical cap
  - Michelson-Morley interferometer
  - Sagnac inteferomter (Sagnac effect)

24

Nomenclature

This chapter contains a summary with simple description of most occurring symbols used in this textbook.

Let us start first with the Greek letters:

α `alpha`
β `beta`
γ `upsilon`
δ `delta`
ϵ `epsilon`
ε `varepsilon`
ζ `zeta`
η `eta`

θ `theta`
ϑ `vartheta`
ξ `xi`
κ `kappa`
λ `lambda`
μ `mu`
ν `nu`

o `o`
π `pi`
ϖ `varpi`
ρ `rho`
ϱ `varrho`
σ `sigma`
ς `varsigma`

τ `tau`
υ `upsilon`
ϕ `phi`
φ `varphi`
χ `chi`
ψ `psi`
ω `omega`

Γ `Gamma`
Δ `Delta`
Θ `Theta`

Λ `Lambda`
Ξ `Xi`
Π `Pi`

Σ `Sigma`
Υ `Upsilon`
Φ `Phi`

Ψ `Psi`
Ω `Omega`

Table 24.1: Greek letters

And finally the most occurring mathematical operators and objects:

Symbols	Descriptions
(	Opened parenthesis
)	Closed parenthesis
[	Opened bracket
]	Closed bracket
{	Opened brace
}	Closed brace
$]\ldots,\ldots[$	Opened interval
$[\ldots,\ldots]$	Closed interval
$]\ldots,\ldots]$ $[\ldots,\ldots[$	Semi-opened (or semi-closed) intervals
$\lfloor x \rfloor$	Floor of x, round down to nearest integer

Symbols	**Descriptions**
$\lceil x \rceil$	Ceiling of x, round up to nearest integer
$[x]$	Integer value of a number
$\{x\}$	Fractional value of number ($[x] = x - \{x\}$)
$\{\ldots\}$	Content of a set
$\wedge$	AND operator, denoted & in computer science and corresponding to multiplication in maths
$\vee$	OR operator, denoted sometimes ǁ in computer science
$\varnothing$	Empty Set
$\therefore$	Therefore
$\because$	Because
$\Rightarrow$	Implies (in applied maths), if and only if (in logic), nuclear reaction (in atomistic)
$\Leftrightarrow$	Is equivalent
$\neg$	Negation (logical negation)
$\vdash$	Proves that
$\nvdash$	Doesn't proves that
∞	Infinity
$=$	Equality symbol
$\equiv$	Identity symbol (left term is assumed to be equal to the right one and vice-versa)
$\cong$	Approximately equal symbol
$\propto$	Linearly proportional symbol
$:=$, $\triangleq$	By definition symbols (defined as)
$>$	Greater than
$<$	Less than
$\gg$	Much greater than
$\ll$	Much smaller than
$\leq$	Less than or equal to
$\geq$	Bigger or equal to
$\succ$	Preferred to (for utility in econometry) or positive definite matrix in linear algebra
$\prec$	Not preferred to (for utility in econometry) or negative definite matrix in linear algebra
$\succeq$	Preferred or equal to (for utility in econometry) or negative semidefinite matrix in linear algebra
$\preceq$	Not preferred or equal to (for utility in econometry)
$\sim$	Equivalent to (for utility in econometry)
$\rightarrow$	Tends toward to in functional analysis or implies in logic
$\oplus$	In proof theory an abstract way to represent the following three operators $\{\wedge, \vee, \rightarrow\}$, in boolean algebra it is the exclusive OR
$\rightarrowtail\!\!\!\!\twoheadrightarrow$	Surjective symbol
$\rightarrowtail$	Injective symbol
$\leftrightarrow$	Bijective symbol
$\mathcal{T}$	In logic a set of terms
$\mathcal{F}$	In logic a set of formulas
$\mathbb{N}$	Natural numbers set (positive integers)
$\mathbb{N}^*$	Natural numbers set (positive integers) not including zero

Symbols	Descriptions
$\mathbb{Z}$	Relative numbers set (all integers)
$\mathbb{E}$	Even numbers set
$\mathbb{O}$	Odd numbers set
$\mathbb{Q}$	Rational numbers set (ratio of relative numbers)
$\mathbb{R}$	Real numbers set
$\mathbb{C}$	Complex numbers set
$\mathbb{H}$	Quaternion numbers set
i	Pure imaginary number
$\bar{z}$	In statistics the arithmetic average of z or the complex conjugate of z
$\lvert x\rvert$	Absolute value of x or mode of a complex number
$\Re$	Real part of a complex number
$\Im$	Imaginary part of a complex number
$\ker(\ldots)$	Kernel of a function
$\mathrm{Card}(\mathcal{S})$	Cardinal (size) of set $\mathcal{S}$
$\aleph$	Transfinite Cardinal symbol
$\in$	Symbol that means left term belongs to the right term
$\notin$	Symbol that means left term does not belong to the right term
$\subset$	Symbol that means left term (that is a set) is a subset of the set on the right
$\not\subset$	Symbol that means left term (that is a set) is not a subset of the set on the right
$\subseteq$	Symbol that means left term (that is a set) is a subset or a set equal to the set on the right
$\not\subseteq$	Symbol that means left term (that is a set) is not a subset or even a set equal to the set on the right
$\cup$	Symbol that means left term (that is a set) is merged (union) with right term that is also a set
$\sqcup$	Symbol that means left term (that is an interval) is merged (union) with right term that is also an interval
$\cap$	Symbol that means we take only intersection (equal) items of left and right terms that are sets
$\bigcup\limits_{i=1}^{n}$	Union of multiple sets
$\bigcap\limits_{i=1}^{n}$	Intersection of multiple sets
$\mathcal{P}(A)$	All possible subsets of A
A^c	All the items that do not belong to set A
$\vert$	Such that...
$\forall$	For all...
$\exists$	It exists...
$\star$	Generic operation (non-explicit) in set theory
$+$	Addition symbol of two terms
$\sum\limits_{i=1}^{n}$	Summation of multiple indexed terms
$-$	Subtraction symbol of two terms

Symbols	Descriptions
$\times, \cdot$	Multiplication (product) symbol of two terms
$n!$	Factorial function
$\prod\limits_{i=1}^{n}$	Multiplication (product) symbol of multiple indexed terms
$\div, /, :$	Symbols for division of two terms depending on school level
$\mid$	Can be divided in Euclidean division (when the left term can divide the right term)
$\nmid$	Cannot be divided in Euclidean division
$\sqrt{\ldots}$	Square root
$\sqrt[n]{\ldots}, (\ldots)^{1/n}$	Common notations for the n-root
$\equiv$	Congruence
mod	Modulus
$[x]_m$	Set of integers congruent to a modulo m
A_n^m	Number of arrangements with repetitions
A_m^n	Number of arrangements without repetitions
Γ_p^n	Simple combination with repetitions
$C_k^n, \dbinom{n}{k}$	Binomial coefficient notation[1] defined by $n!/(k!(n-k)!)$
$\vec{x}$	A vector
$\text{proj}(\ldots)$	Projection operator of a vector
$\lVert\vec{x}\rVert$	Norm of a vector $\vec{x}$
$\ln(\ldots)$	Natural logarithm (base e) of a number
$\log(\ldots)$	Base 10 (if not indicated) logarithm of a number
$e, \exp$	Different notations for the exponential (euler number)
P	Depending on the context this is a probability, cumulated probability or part of a set or a proposition (in proof theory)
$/, \mid$	In the field of bayesian analysis these symbols mean "being known", or "knowing that"
$\mathrm{E}(\ldots),\mu$	In statistics the expected (arithmetic) mean
μ_g	In statistics the geometric mean
μ_h	In statistics the harmonic mean
$\mathrm{V}(\ldots), \sigma^2$	In statistics the biased variance (σ being the biased standard deviation)
M_e	The median (middle value)
M_0	The mode (modal value)
γ	The skewness
κ	The kurtosis
$\hat{x}$	In physics the amplitude of x, in statistics an (unbiased) estimator of x, in geometry a vertex x
Δ	Discriminant of a polynomial in calculus, mediator in geometry, focal length in projective geometry
$\times$	If left and right terms are vectors, this is the cross product (vectorial product)

---

[1] This textbook doesn't respect the ISO notation for this coefficient for recall!

Symbols	Descriptions
$\circ$	If left and right terms are vectors, this is the dot product, also named "inner product" or "scalar product". Otherwise if used with functions, this is the symbol of composition
$\langle \ldots, \ldots \rangle$	Inner product between function
d, ∂	Exact and partial differentials
$\mathcal{C}^n$	Differentiability (continuity) order of a function
$\mathrm{d}f/\mathrm{d}t$ $\mathrm{d}_t f(t)$ f' $\dot{f}$	Common notations for the derivative of a function f
$\mathcal{O}(\cdot)$	Big-O roughly means order of magnitude, order or complexity in computer science
$\vec{\nabla}(f)$ $\vec{\nabla} \cdot f$ $\vec{\nabla} f$ $\overrightarrow{\text{grad}}(f)$	All common notations for the gradient of a scalar field
$\vec{\nabla}(\vec{f})$	Gradient of a vector field
$\vec{\nabla} \circ \vec{f}$ $\text{div}(\vec{f})$	All common notations for the divergence of a vector field
$\vec{\nabla} \times \vec{f}$ $\text{rot}(\vec{f})$	All common notations for rotational (curl) of a vector field
$\Delta \cdot f$ $\vec{\nabla}^2 f$ $\vec{\nabla} \circ (\vec{\nabla} \cdot f)$	All common notations for for the Laplacian of a scalar field
$\Delta \vec{f}$	Laplacian of a vector field
$\Box = \dfrac{1}{c^2}\dfrac{\partial^2}{\partial t^2} - \Delta$	Alembertian
$\diamond$	Vectors elements-wise multiplication (ie Hadamard product)
$\displaystyle\int$	Riemann primitive
$\displaystyle\int\limits_a^b$	Riemann integral in range $[a, b]$
$\displaystyle\oint$	Closed non-oriented curvilinear integral (line integral)
$\displaystyle\ointclockwise$	Clockwise path integral
$\displaystyle\ointctrclockwise$	Counter-clockwise path integral
$\text{Res}[f(z); z_0]$	Residue on z_0 of a function $f(z)$
$*$	Convolution of matrices or functions
D	Covariant derivative (parallel transport) or Fermi-Walker derivative
$M_{m \times n}(\mathcal{S})$	Notation for a matrix of size $m \times n$ with component in $\mathcal{S}$, where $\mathcal{S}$ can be $\mathbb{N}$, $\mathbb{R}$,$\mathbb{C}$
$M_n(\mathcal{S})$	Notation for a square matrix of size n with component in $\mathcal{S}$, where $\mathcal{S}$ can be $\mathbb{N}$, $\mathbb{R}$,$\mathbb{C}$
M_{ij}	Element of the row i and column j of a matrix

Symbols	Descriptions
$M_{:,j}$,$M_{.j}$,col$_j(M)$	The j-th column of a matrix
$M_{i,:}$,$M_{i.}$	The i-th row of a matrix
0_{mn}, $\mathbf{0}$, $\mathbb{O}$	Common notations for a matrix with only zeros as components
I_n, $\mathbb{1}_n$	Unity square (identity) matrix (diagonal with 1, 0 everywhere else) of dimension $n\times n$ or vector of only 1 as components of dimension n
tr(A)	Trace of a matrix
σ	Permutation function
$\mathcal{S}_n$	Set of all permutations of n elements
$D(A)$ det(A) $X(\mathrm{i}\omega)$ $\|A\|$	Common notations for the determinant of a matrix
diag(A)	Diagonal vector extracted from matrix A
A^-	Pseudo-inverse of a matrix
$\vec{x}^T$, A^T	Transpose of a vector $\vec{x}$ or matrix A
$A^\dagger$	The conjugate and transpose matrix A
rk(M)	Rank of a matrix M (dimension of the vector space generated (or spanned) by its columns)
adj(M)	Adjugate (classical adjoint), i.e. transpose of its cofactor matrix, of a square matrix M
δ_{ij},δ^{ij}	Covariant and respectively contravariant (2D) Kronecker symbol
$\varepsilon_{ij},\varepsilon^{ij}$	Covariant and respectively contravariant (2D) Levi-Civita symbol
g_{ij},g^{ij}	Covariant and respectively contravariant metric tensor
η_{ij},η^{ij}	Covariant and respectively contravariant minkowski metric tensor
E^n,E_*^n	n-dimensional space and it's dual space
$\mathcal{E}^n,\mathcal{E}_*^n$	n-dimensional Euclidean space and it's dual space
$\mathcal{P}$	Symbol of a plane (in geometry) or partitions of a set (in measure theory)
$\mathcal{H}^n$	n-dimensional Hilbert space
$\otimes$	Tensor product or Kronecker product (depending on the context...), i.e. matrix cross-correlation
Γ_{ki}^j	Christoffel symbols of the second kind
Γ_{kij}	Christoffel symbols of the first kind
∇_j,∂_j	Covariant derivative for 1-forms
$R_{i,jk}^l$	Riemann-Christoffel symbol
R_{ij}	Ricci curvature
R	Ricci scalar
$G_{\mu\nu},G^{\mu\nu}$	Covariant and respectively contravariant Einstein tensor
$:$	When the left term is a matrix at the right one a vectors, this is "Frobenius (matrix) dot product" or "Frobenius inner product"
$\mathcal{F}(x(t))$ $\mathcal{F}(x(t))(\omega)$ $X(\mathrm{i}\omega)$ $X[k]$	Most common notations for the Fourier transform of $x(t)$
$\mathcal{F}^{-1}(F(\omega))(t)$ $\mathcal{F}^{-1}(X[k])$	Most common notations for the inverse Fourier transform
$\mathcal{F}[x[m]]$	Discrete Fourier transform of $x[m]$

Symbols	Descriptions
$\mathcal{F}^{-1}[X[n]]$	Inverse discrete Fourier transform of $X[n]$
$\mathcal{L}(x(t))$	Laplace transform
$\mathcal{L}(X(s))$	Inverse Laplace transform
$\mathcal{UL}(x(t))$	Unilateral Laplace transform
$\mathcal{Z}[x[n]]$	Forward bilateral $\mathcal{Z}$-transform
$\mathcal{Z}^{-1}[X[z]]$	Inverse $\mathcal{Z}$-transform
$\mathcal{UZ}[x[n]]$	Unilateral $\mathcal{Z}$-transform
$\perp$	Perpendicular to
$\overline{AB}$, AB	Segment A to B
$\widehat{AB}$	Angle between A and B
$\mathcal{S}^n$	n-dimensional surface of a $n+1$ dimensional sphere
$\arg\min_x f(x)$ $\min_x f(x)$ $\arg\max_x f(x)$ $\max_x f(x)$	Respectively the value of x that minimize/maximize $f(x)$
ΔABC	A triangle made with three points A, B and C
$R_{\text{axe}}, T_{\text{axe}}, S_{\text{axe}}$	Rotation, translation or symmetry operators along a given axe
$K_{p,q}$, K_n	The first denotes a bipartite graph and the later a complete graph
$D=\gamma^{\mu}\partial_{\mu} \equiv \not{\partial}$	Feynman's slash notation (i.e. Dirac operator)
♁	Symbol in astronomy and astrophysics to refer to the Earth
$\odot$	Symbol in astronomy and astrophysics to refer to the Sun
${}_{Z}^{A}\mathrm{X}_{N}$,, ${}^{A}\mathrm{X}$	Two common notations for a chemical element of mass number A, atomic number Z and number of neutrons N
$\rightleftharpoons$	Double harpoon (reversible reaction in chemistry)
$\rightharpoonup$	Simple harpoon (non-reversible reaction in chemistry)

For a summary of the physical and chemical constants, the reader must refer to the section of Mechanics page 3113.

6.163 Unit Sphere 2146
6.165 Plane symmetry of a vector relatively to a plane 2153
6.167 Spinor full rotation (special example) 2160

7.1 Typical representation example of an oriented infinite axis with origin 2177
7.2 Position of a point in a cartesian plane 2178
7.4 Vocabulary planar graph 2180
7.5 Representation of roots on a planar graph 2182
7.6 Example of step-wise function for swiss coordinate wage in Maple™ 4.00b . 2183
7.7 Example of typical histogram in engineering companies (Six Sigma) 2184
7.8 Example of OHLC (candlestick plot) time series with moving averages in financial trading 2184
7.9 Quadrants in a 3D orthogonal system 2186
7.10 Mutually perpendicular planes in $\mathbb{R}^3$ 2187
7.11 Right-handed coordinate system 2187
7.12 Grid representation of a 3D function in Maple™ 4.00b 2188
7.13 Shading interpolation representation of a 3D function in Maple™ 4.00b . . . 2189
7.14 Isolines representation of a 3D function in Maple™ 4.00b 2189
7.15 Better representation of a 3D function in Maple™ 4.00b 2190
7.17 Representation of a section of the pseudo-3D surface 2192
7.18 Representation of multiple sections of the pseudo-3D surface 2192
7.20 Scenario of thee points in a plane 2194
7.21 Example of symmetry through the y-axis of a function 2196
7.22 Example of symmetry through the x-axis of a function 2197
7.23 Example of symmetry through the origin O of a function 2197
7.24 Example of a positive vertical translation of a function 2198
7.25 Example of a negative vertical translation of a function 2198
7.26 Example of negative horizontal translation of a function 2199
7.27 Example of positive horizontal translation of a function 2200
7.28 Example of vertical stretch of a function 2201
7.29 Example of vertical compression of a function 2201
7.30 Example of horizontal stretch of a function 2202
7.31 Example of horizontal downscale of a function 2202
7.32 Summary of some of the types of monocities of univariate functions 2204
7.33 Most common types of charts 2205
7.35 Quick summary of applications/functions types 2210
7.36 Example of a very simple periodic function with period and amplitude 2211

7.37 Example of an even function 2212
7.38 Example of an odd function 2213
7.39 Univariate affine and linear function 2215
7.40 Different plots of simple power functions 2216
7.41 Different plots of simple exponential functions $(1^x, 2^x, 3^x, 4^x)$ in Maple™ 4.00b 2218
7.42 Different plots of logarithm $\ln(x) = \ln_e(x)$ in green and $\log_{10}(x)$ in red with Maple™ 4.00b 2219
7.43 Different plots of trigonometric functions in Maple™ 4.00b 2219
7.46 Some polynomials plotted with TikZ 2220
7.47 Example of a rational function 2221
7.48 Example of a step function 2222
7.49 Geometric concept of limit in $\mathbb{R}^3$ 2226
7.50 Left and right limit examples 2228
7.51 Graphical representation of a horizontal and vertical asymptote 2270
7.52 Graphical representation of an oblique affine asymptote 2272
7.53 Graphical representation of a parabolic branch example following x-axis 2273
7.54 Graphical representation of a curvilinear asymptote 2274
7.55 Basic techniques for finding limits 2275
7.56 Common types of discontinuities 2276
7.57 Example of a famous oscillating discontinuity 2278
7.58 Epigraph and Hypograph of a function 2281
7.61 Double logarithmic grid 2288
7.62 Simple horizontal logarithmic grid 2288
7.63 Graphical representation of the correspondence between the natural logarithm and the exponential 2289
7.64 Discrete convolution example 2296
7.65 Matrix Convolution 2300
7.66 Most common types of integral transforms with harmonized notation 2304
7.67 Example of a simple complex conformal mapping 2364
7.68 Example of a complex function (conformal mapping) 2391
7.69 $\mathbb{C}$-linear application example 2392
7.72 Practical Maple™ 17.00 example of simple C-linear application 2395
7.73 Transformation into polar coordinates of an ellipse 2396
7.74 Result of the Joukovski transformation in polar coordinates 2397
7.75 Important application example of the Joukovski function 2398
7.77 Plane representation of a well known holomorphic function... 2404
7.79 Representation of an important holomorphic function with its isolines 2407
7.80 Complex Logarithm plot in Maple™ 4.00b 2409
7.81 Complex Logarithm with TikZ 2410
7.83 Divergent Maclaurin series 2421
7.85 Representation of the various convergence of radius of $h(z)$ 2423
7.86 Focus on the complex representation to understand the reason for the divergence 2424
7.88 Representation of the deformation of a disc in a crown/ring 2426
7.89 Representation of a closed path with round trip 2427
7.91 Laurent series representation of $f(z)$ in Maple™ 4.00b 2436
7.92 Sum of the two Laurent series of $f(z)$ for both singularities in Maple™ 4.00b 2437
7.93 Essential singularity example with $e^{1/z}$ in Maple™ 4.00b 2439
7.94 Multiple isolated singularities surrounded by curvilinear paths 2442

7.95 Example of ultrametric distance with an orgchart 2451
7.96 Common types of distances 2455
7.97 Example of Lipschitz function 2459
7.98 Uniform continuity illustrated 2461
7.99 An open ball of radius r, centered at the point x 2464
7.100 Examples of closed balls of unit radius with different distances 2466
7.102 High-school example of a Hausdorff distance in the plane 2472
7.103 A naive maps homeomorphisms 2474
7.104 A more complete maps homeomorphisms 2474
7.105 Intuitive maps homeomorphism 2475

8.1 Schematic definition of the radian 2504
8.2 A chart to convert between degrees and radians 2505
8.4 Degrees, minutes of arc, seconds of arc 2506
8.5 Construction idea of elementary (circle) trigonometric functions 2508
8.6 Design principle of common circle trigonometric functions 2510
8.8 Remarkable angles of common circle trigonometric functions 2512

8.149 Various intersections between a cone and a plane 2770
8.150 Shock wave intersecting the ground 2770
8.151 Maple™ 4.00b plot to obtain a parabola by the intersection of a cone and a plane 2771

8.152 Maple™ 4.00b plot to obtain a hyperparabola by the intersection of a cone and a plane . . . 2772
8.153 Maple™ 4.00b plot to obtain an ellipse by the intersection of a cone and a plane 2773
8.154 Maple™ 4.00b plot to obtain a circle by the intersection of a cone and a plane 2773
8.155 Definition of the focus (F), direction (D) of the conical and eccentricity (e) . 2775
8.156 Representation of the parameters of the conical for the parabola . . . 2777
8.157 Parabola = set of points equidistant from L and F . . . 2777
8.158 Representation of the parameters of the conical for the ellipse . . . 2781
8.159 Hand-made construction of an ellipse . . . 2783
8.160 Apogee and Perigee . . . 2786
8.161 Representation of the parameters of the conical for the hyperbola . . . 2788
8.162 Dandelin Sphere . . . 2793
8.163 Positive definite, positive-semidefinite and indefinite matrices visual representation . . . 2799
8.164 Example of a plane in Maple™ 4.00b . . . 2802
8.165 Representation of the search of the distance from a point to a line . . . 2807
8.166 FG-squircle representation in Maple™ 4.00 . . . 2813
8.167 Epicycloid path . . . 2816
8.168 Epicycloid sketch for proof . . . 2817
8.169 Archimedean Spiral . . . 2818
8.170 Exponential spiral in 2D and 3D of the type r_0e^{bt} . . . 2819
8.171 Boost-glide atmospheric re-entry . . . 2819
8.172 Hypocycloid path . . . 2822
8.174 Representation of a cone . . . 2823
8.176 Parametric representation of a cone in Maple™ 4.00b . . . 2825
8.177 Representation of a $\mathcal{S}^2$ sphere . . . 2826
8.179 Parametric representation of a sphere in Maple™ 4.00b . . . 2827
8.180 A great circle divides the sphere in two equal hemispheres . . . 2828
8.181 Representation of an ellipsoid . . . 2834
8.183 Parametric representation of an ellipsoid in Maple™ 4.00b . . . 2835
8.184 Oblate spheroid (on the left), Prolate spheroid (on the right) . . . 2836
8.186 Parametric representation of a cylinder in Maple™ 4.00b . . . 2838
8.188 Parametric representation of a paraboloid in Maple™ 4.00b . . . 2840
8.190 Hyperbolic Rules Surface . . . 2843
8.191 Hyperbolic Circles Surface . . . 2843
8.192 Parametric representation of a hyperboloid of one sheet in Maple™ 4.00b . . 2844
8.193 Two hyperboloids (of one sheet and two sheets) which are asymptotic to an identical elliptic cone . . . 2845
8.194 Common conical surfaces . . . 2847
8.195 Parametric representation of a torus in Maple™ 4.00b . . . 2849
8.196 Parametric curve and parametric surface . . . 2851
8.197 Parametric representation of an helix in Maple™ 4.00b . . . 2856
8.200 Plot of the isoclines in MATLAB® 5.0.0.473 . . . 2858
8.201 Projection of the isoclines in MATLAB® 5.0.0.473 . . . 2859
8.202 Plane representation of isoclines with coloured gradients in MATLAB® 5.0.0.473 . . . 2859
8.204 Isoclines association projected with color gradients in MATLAB® 5.0.0.473 . 2860
8.207 Representation of an osculating circle . . . 2867

8.208 Representation of the trihedron . . . 2869
8.213 Representation of a surface patch . . . 2879
8.214 Example of an arbitrary plane polygon . . . 2888
8.215 Example of a crossed polygon . . . 2889
8.216 Example of a concave polygon . . . 2890
8.217 Example of a convex polygon . . . 2890
8.218 Example of a polygon (pentagon with 5 edges and 5 vertices) . . . 2891
8.219 Pentagon with all its 10 segments . . . 2891
8.220 Example of segments starting from a chosen point . . . 2892
8.223 Some regular polygons (subfamily of convex polygons) . . . 2893
8.224 Example of rectangle . . . 2894
8.225 Example of square . . . 2895
8.226 Example of an unspecified triangle with inscribed circle and bisectors . . . 2896
8.227 Unspecified triangle divided into two right triangles . . . 2896
8.228 Reminder of the construction for the cosine's theorem proof . . . 2897
8.230 Example of isosceles triangle . . . 2900
8.231 Right angle isosceles triangle . . . 2901
8.232 Equilateral triangle . . . 2902
8.233 Illustrative figure for Viviani's theorem . . . 2904
8.234 Example of a right angle triangle . . . 2905
8.235 Example of trapezoid . . . 2906
8.236 Quadrilateral hierarchy (including Trapezoid classification) . . . 2907
8.237 Parallelogram example . . . 2908
8.239 A regular hexagonal grid . . . 2909
8.240 James Webb Space Telescope . . . 2910

8.296 Graphs basic vocabulary 3000
8.297 Simple Graphs 3000
8.298 Example of a multigraph 3001
8.299 Example of planar graphs 3002
8.300 Graph with 2 faces, 4 vertices and 4 nodes 3002
8.301 Tree with one edge and two vertices 3003
8.302 Graph with at least one cycle 3003
8.303 Regular polygons seen as graphs 3004
8.304 Example of graphs subsets 3007
8.305 A few possible 2-regular graphs 3008
8.306 Examples of subgraphs and induced graphs 3009
8.308 Example of complete graphs 3010
8.309 Star of David 3011
8.310 Star of David completed 3011
8.311 Stable subgraph example 3012
8.312 Simple path example 3012
8.313 Various connected graphs 3014
8.314 Example of a spanning tree 3015
8.315 Example of a minimum spanning tree 3015
8.316 PERT (Program Evaluation Review Technique) diagram 3017
8.317 Same graph but seen in Microsoft Project 97 3017
8.318 Examples of cyclic graphs 3018
8.319 Example of a connex graph containing a cycle 3018
8.320 Example of a connex graph containing no cycles 3018
8.321 Example of a forest (3 connex graphs) 3019
8.322 Example of Hamiltonian or Non-Hamiltonian graphs 3020
8.323 Antique map of the city of Königsberg 3020
8.324 Königsberg equivalent graph 3021

8.325 Example of complementary graph . . . 3023
8.326 Example of self-complementary graph . . . 3023
8.327 Example of a $K_{3,3}$ bipartite graph . . . 3023
8.328 Isomorphic graphs with their adjacency matrix . . . 3024
8.329 Example of Markov chain (nor antireflexive or symmetric) . . . 3026
8.331 Example of graph of categories . . . 3032
8.332 Braid and corresponding string (node diagram) . . . 3035
8.333 Particular presentation of a braid . . . 3036
8.334 Example of the problem of the braid representation . . . 3036
8.336 First example of invariant braid . . . 3036
8.337 Second example of invariant braid . . . 3037
8.338 Translation of crossing and preserving the trivial invariance . . . 3037
8.339 Length invariance . . . 3037
8.340 Example of multiplication of two braids . . . 3037
8.341 Check of associativity of braids (by the multiplication) . . . 3038
8.342 Control of the commutativity of braids (by multiplication) . . . 3038
8.343 Check of the existence of a neutral element for braids (by the multiplication) 3038
8.344 Check of the existence of an inverse element for braids (by the multiplication)3039
8.345 Indexing braids tendrils . . . 3039
8.346 Indexation convention . . . 3039
8.347 Indexation tendril trap . . . 3039
8.348 Difference between tendril and cross . . . 3040
8.349 Braid and corresponding string (node diagram) . . . 3040
8.350 Example of a node in real life . . . 3041
8.351 Knot representation by mathematicians . . . 3041
8.352 Equivalence between an open and a closed knot . . . 3041
8.353 2 different perspectives of the same trefoil knot . . . 3042
8.354 Trefoil plot . . . 3042
8.355 Searching for equality between mirror symmetry of the clover node . . . 3042
8.357 Example of a Perko pair . . . 3043
8.358 Knots that are simply an unknot . . . 3043
8.359 Refresh of the definition of the multiplication of two knots . . . 3044
8.360 Check of the commutativity of knots (by the multiplication) . . . 3044
8.361 Check of the existence of a neutral element for the knots (by the multiplication)3044
8.362 Check of the commutativity of knots (by the multiplication) . . . 3045
8.363 Check of the existence of an inverse element for the knots (by the multiplication)3045
8.365 Conway knot . . . 3047
8.366 Example of a succession of knots on an open knot . . . 3049
8.367 Separation of the knot . . . 3049
8.368 Tait's classification . . . 3050
8.369 Knotted knot? . . . 3052
8.371 Trivial Knot . . . 3053
8.372 Trefoil Knot . . . 3053
8.373 Example of RNA or DNA strand . . . 3054
8.374 Mirror image by crosses inversion . . . 3056
8.375 Mirror of trefoil knot . . . 3056
8.376 Simplistic application example of the Reidemeister movements . . . 3057
8.377 Knot isotopie . . . 3058

8.378 Interlaces with three convex components . . . 3059
8.379 Example of associated interlaces . . . 3059

12.247 Pseudo-3D (wrong) common visualization of gravitational wave of a binary system 5863
12.248 Gravitational cosmic background "radiation" 5866
12.249 Summary of the most well-known experimental tests of General Relativity . . 5868
12.250 Copenhagen survey on how the "Big Bang" should be understood 5881
12.251 Automated Plate Measurement (APM) Galaxy Survey 5882
12.252 Illustration of the validity limit of the model 5884
12.253 Illustration of the inflated balloon Universe model 5886
12.254 Evolution of Hubble parameter estimations 5889
12.255 An artistic concept of the Hubble Horizon 5891
12.256 Illustration of the different types of universes 5899
12.257 Illustration of what would give observations depending on the curvature type 5901
12.258 Comparison of CMB results from COBE, WMAP and Planck 5901
12.259 Universe fluctuation density scales 5902
12.260 Evolution of the scale factor for a zero curvature space 5906
12.262 Various estimations of our Universe age 5918
12.264 Big Bang and Big Crunch plot side by side 5926
12.265 Big Bounce artistic illustration 5929
12.272 Summary of Newtonian Universe models 5946
12.273 Artist's logarithmic scale conception of the observable Universe 5947
12.274 Hubble Ultra-Deep field 5952
12.275 Universe scales 5953
12.276 Simplified illustration of the observable Universe 5954
12.277 Simplified illustration of the neighboring superclusters 5955

12.278 Simplified illustration of the Virgo supercluster 5956
12.279 Simplified illustration of our Local Group 5957
12.280 Simplified illustration of satellite galaxies 5958
12.281 Simplified illustration of the Milky Way Galaxy 5959
12.282 Simplified illustration of the Orion Arm 5960
12.283 Simplified illustration of the solar neighbourhood 5961
12.284 Simplified illustration of the nearest stars 5962
12.285 Observable Universe map 5965
12.286 Cosmic microwave background according to WMAP 5-year results 5966
12.287 CMB experiment looking a maze of contaminants (credit: Josquin Errard) . . 5967
12.288 FIRAS CMB Black Body radiation spectrum 5968
12.289 2D illustration of (speculated) Universe past history following 121st century hypothesis 5969
12.291 Big Bang recombination 5978
12.292 Ionization factor and mean free path in function of temperature 5983
12.293 ΛCDM theory experimental evidence 5987
12.294 DESI galaxies survey (credit: DESI collaboration and KPNO/NOIRLab/NSF/AURA/R. Proctor) 5993
12.295 Matter density Ω_m statistical distribution of different experiments 6011
12.297 Cosmological models summary 6048
12.298 Uchuu 12021 Universe simulation 6049
12.299 Idea of Universe inside a (Schwarzschild) Black Hole 6059
12.300 Copenhagen survey on matter fate in a Black Hole 6060
12.301 Okun wheel 6073
12.302 Mass-period diagram of confirmed discovered exoplanets in 12015 6078
12.303 Various universes popping-up from the Cosmos false vacuum 6096
12.304 Illustration of Dp-branes 6103
12.305 Universe surface generated by respectively an opened/closed string 6104
12.306 Elementary illustrated refresh of a parametric curve 6105
12.307 Configuration for the study of an elementary surface element 6107
12.308 Parametrization of a space-time surface 6110

13.3 Wave functions and probability density of a one-dimensional harmonic oscillator 6129
13.4 Probability density function of a one-dimensional harmonic oscillator for large n 6130
13.5 Legendre spherical harmonics plot 6142
13.6 Plot of the spherical harmonics $Y_{1,2}$ 6169
13.7 $1s$ density map 6169
13.8 $2p$ orbitals (spherical harmonics) 6169
13.9 $2p$ density map 6170
13.10 $3d$ orbitals (spherical harmonics) 6170
13.11 $3d$ density map 6170
13.12 $3d$ orbitals (spherical harmonics) 6171
13.13 $4f$ density map 6171
13.15 Plot of a few radial functions $R_{n,l}(r)$ 6180
13.16 Probability of finding the electron as a function of distance from the nucleus for the hydrogen atom in the $1s$ state 6186

13.17 Hydrogen atoms imaged at four energy levels 6186
13.18 Plot of the effective potential energy in Maple™ 4.00b for various l and Z . . 6187
13.19 Plot of the famous effective potential energy in Maple™ 4.00b for $l = 1$ and $Z = 1$ 6188
13.20 Plot of the effective potential energy for $l = 1$ and various Z 6189
13.21 Force Atomic Microscope image of chemical bonds of a nanographene molecule C60 6190
13.22 Example ofa molecule where almost everything is moving 6192
13.23 Simplified study of the dihydrogen cation H_2^+ 6202
13.24 Energy levels of dihydrogen cation H_2 6204
13.25 Construction for the study of inertia momentum of a diatomic molecule . . . 6207
13.26 Harmonic oscillator with two masses 6211
13.27 Various energies and corresponding radiation involved in some chemical/molecular phenomenon 6215
13.28 Most common classical and exotic states of matter 6229
13.29 Homogeneous mixture, heterogeneous mixture, compound or element 6230
13.30 Acute Toxicity of some ingredients/molecules 6232
13.31 Acute Toxicity of some ingredients/molecules 6233
13.32 Steps in Analytical Chemistry 6234
13.34 The joy of mixtures... 6236
13.35 The joy of mixtures for dyers and military 6237
13.36 Example of polymorph 6240
13.37 National Fire Protection Agency (NFPA) hazard diamond 6241
13.38 Some typical chemical reactions 6243
13.39 Some typical contrails 6244
13.40 Limiting reactant illustration 6246
13.42 Kirchhoff's enthalpy law illustration 6263

14.1 Floating point (real numbers) in simple precision 6277
14.2 Floating point (real numbers) in half precision 6278
14.3 Big $\mathcal{O}$ notation complexities plot 6287
14.4 The illustrated principle of Archimedes algorithm 6298
14.5 Comparison of logarithmic formulations using Stirling formula 6302
14.6 Synoptic summary and relationships between various regression models . . . 6320
14.7 Graphical representation of respectively SST, SSE, SSR 6331
14.8 Some values of the linear correlation coefficient 6333
14.9 Graphical representation of an univariate regression with the ANOVA approach in Microsoft® Excel® 14.0.7177 6342
14.10 Lack of fit and pure error 6346
14.11 Graphical representation of the idea behind the Gaussian linear regression . . 6349
14.12 Examples of "plot" of residuals 6350
14.13 Print screen of a confidence interval obtained with Minitab 15 6363
14.14 Print screen of a prediction interval (PI) obtained with Minitab 15 6365
14.15 Confidence vs Prediction interval 6365
14.16 Outliers vs Influential points 6392
14.17 Importance of an influential point on regression equation 6395
14.18 Some famous techniques of cross-over validation 6429
14.19 K-fold cross-over validation 6430

14.23 Confusion matrix Minitab 15.0 output example 6461
14.24 Precision and Recall 6483
14.25 Four-fold plot with R 3.4.2 6502
14.26 Odds Ratio and Risk Ratio range values subjective qualifications 6506
14.27 Risk Ratio (relative risk), Odds Ratio or Hazard Ratio rules 6508
14.32 Corresponding values of the construction of the confusion matrix 6515
14.33 Confusion matrix with Minitab 16.1.1 6516
14.34 ROC curve with Minitab 16.1.1 6516
14.35 Values of the confusion matrix for various cutoff values 6517
14.36 ROC curves 6518
14.42 Overview of all constructed columns for the lift curve 6528
14.45 Underlying idea of the Normal GLM 6532
14.46 Underlying idea of the Poisson GLM 6534
14.47 Underlying idea of the binomial GLM 6538

16.228 Markov chain reliability model example 8757
16.229 Kaplan-Meier typical survival curves in R software 8768
16.230 Graph of the ABC method 8774
16.231 ABC method associated with a Pareto curve 8776
16.233 Principle of construction of centered reduced units 8784
16.234 Two normalized factors study domain example 8785
16.235 Two factors with the response surface 8785
16.236 Generic example of interaction for two factors (hyperbolic paraboloid) 8788
16.239 Two factors with the response surface 8799
16.241 Henry plot of the replicated factorial design with Minitab 17.1.3 8806
16.242 Traditional representation of a full factorial design with 3 factors 8814
16.244 Visual 2^2 factorial design and fractional factorial design 8817
16.245 Display of fractional factorial designs resolutions selector with Minitab 15.1.18820
16.246 Display of fractional factorial designs resolutions selector in Design Expert . 8820
16.247 Representation of a real fractional factorial design with 3 factors 8822
16.248 Taguchi L8 linear graph 8839
16.249 Generic example of interaction for two factors quadratic polynomial 8849

16.250 2D Composite Center Design 8856
16.251 2D Composite Center Design variance perspective plot in Maple™ 4.00b . . 8859
16.252 2D Composite Center Design variance top plot in Maple™ 4.00b 8859
16.253 2D Faced-centered Design variance perspective plot in Maple™ 4.00b 8862
16.254 2D Faced-centered Design variance top plot in Maple™ 4.00b 8862
16.257 Evolutionary solver settings for seeking D-optimal design in Microsoft® Excel® 14.0.7015 8869
16.258 Final D-optimum design following NIST recommendation in Microsoft® Excel® 14.0.7015 8870
16.260 Explicit formulas for index efficiency compliant to NIST in Microsoft® Excel® 14.0.7015 8872
16.261 Index efficiency conforming to NIST in Microsoft® Excel® 14.0.7015 8873
16.262 JMP (SAS) efficiency index of optimal designs 8873
16.263 Three factors mixtures design simplex 8875
16.264 Various arrangements of three factors mixture simplex 8877
16.265 4 factors simplex centroid example 8877
16.266 Three factor mixtures design complex 8880
16.267 Simplex Centroid Design 8893
16.268 Simplex centroid design in each point of a 2^3 full factorial experiment 8894
16.269 2^3 factorial design in each point of a simplex centroid design 8894
16.272 Derringer and Suich desirability functions plot 8902
16.274 Larson's binomial nomograph 8923
16.275 MIL 105E acceptance sampling table 8925
16.276 Binomial, Hypergeometric and Ideal OC for AQL$=2.5\%$ and $n=200$ 8929
16.277 Operating curve summary 8930
16.278 AOQ (Average Outgoing Quality) binomial chart $A=30$, $n=700$ 8933
16.279 Naive control chart 8934
16.280 Run Chart with Minitab 17.1.3 8935
16.283 Minitab control chart wizard 8943
16.284 iSixSigma control chart wizard 8943
16.286 $\bar{X}$ control chart operating characteristic curve 9047
16.287 Pacific Northwest National Laboratory automatic long-term performance measurement equipment 9050

16.289 Binomial sample size demonstration plan in Weibull++ 7 software 9054
16.290 Weibull reliability sample size with Weibull++ 9056
16.291 Weibull reliability test time with Weibull++ 9057
16.292 Weibull reliability sample size for MTBF test with Weibull++ 9058
16.293 Beta-Binomial sample size demonstration plan in Weibull++ 7 software . . . 9061

List of Tables

4.1 Methodology for Maths & Physics developments . . . 51
4.2 Reminder of the difference scale of Sources in Sciences . . . 61

5.1 Truth table of values . . . 145
5.2 Truth table of explicit values . . . 145
5.3 Truth table of binary values . . . 145
5.4 `OR` inclusive truth table . . . 146
5.5 `OR` exclusive (XOR) truth table . . . 146
5.6 `AND` truth table . . . 147
5.7 Implication truth table . . . 148
5.8 Truth table of the equivalence . . . 151
5.9 Summary of logical core operators . . . 155
5.10 Truth table of main logical operators . . . 155
5.11 Basics Deductive Logical Laws - Common Implications and Equivalences . . 156
5.12 Combination of propositional variables . . . 158
5.13 Consistency, Completeness, Decidability of common axiomatic systems . . . 194
5.14 Common symbols in Classical Logic and Proof Theory . . . 201
5.15 Most well known rules of inference and fallacies in Classical Logic . . . 202
5.16 Some well known basic variables transformations . . . 239
5.17 Greek Alphabet . . . 280
5.18 Summary of typical domain of definitions in Switzerland . . . 282
5.19 Summary of typical domain of definitions according to ISO norms . . . 283
5.20 Binary Relations . . . 291
5.21 Laws and their properties in $\mathbb{N}$ . . . 420
5.22 Laws and their properties in $\mathbb{Z}$ . . . 422
5.23 Laws and their properties in $\mathbb{Q}$ . . . 424
5.24 Summary of most common algebraic structures . . . 435
5.25 Some famous probabilities (and estimations) values . . . 474
5.26 Classical cases of probabilities . . . 481
5.27 Resume of main Combinatorial Analysis cases . . . 532
5.28 Identification of the median . . . 551
5.29 Identification of the median and the mode . . . 554
5.30 Identification of the mediale . . . 562
5.34 Marginal Mean example . . . 576
5.36 Qualitative judgements of C.Vs commonly accepted . . . 589
5.37 Anscombe's quartet . . . 609
5.38 Anscombe's quartet statistics summary . . . 610
5.39 Bradford Hill correlation-causation criterion . . . 617
5.40 Interpretation for kappa or ICC inter-rater agreement . . . 632
5.41 Sigma quality level with defection / non-defection rate . . . 703

5.44 Occurrence of a digit following the Benford distribution . . . 803
5.45 Summary of most common discrete distributions . . . 815
5.46 Summary of most common continuous distributions . . . 815
5.47 One question survey sample size with fpc factor . . . 876
5.49 Interpretations of the Bayes Factor . . . 915
5.50 Chebychev typical intervals to the mean . . . 922
5.51 Conversion sigma to p-value in unilateral . . . 952
5.52 Conversion sigma to p-value in bilateral . . . 952
5.53 Typical "cross" table of a one factor ANOVA . . . 1007
5.54 One-way fixed factor ANOVA table . . . 1018
5.63 Typical cross structure for the analysis of variance of 2 fixed factors without repetitions . . . 1040
5.64 Two-way fixed factor ANOVA table without repetitions . . . 1043
5.65 Typical cross structure for the analysis of variance of 2 fixed factors with repetitions . . . 1045
5.66 Two-way fixed factor ANOVA table with repetitions . . . 1050
5.68 Hierarchical (random) factor ANOVA table . . . 1071
5.69 Hierarchical (fixed) factor ANOVA table . . . 1072
5.71 One-way blocked ANOVA table . . . 1074
5.73 Latin square ANOVA table . . . 1080
5.74 Graeco-Latin square of order 4 . . . 1082
5.75 Greaco-Latin square ANOVA table . . . 1090
5.76 Summary of some naive parametric tests/statistics and their nonparametric equivalent . . . 1154
5.89 Flexible distribution-free & robust testing common hypotheses about numerical data (author: Adrian Olszewski) . . . 1192
5.90 Tabulated values of the Hartley constant $d_2(n)$ . . . 1205
5.91 Tabulated values of the $d_3(n)$ constant . . . 1206
5.92 Generic representation of a P.C.A. table . . . 1214
5.94 Contingency table (crosstab) of CFA . . . 1233
5.95 Joint frequency table of CFA . . . 1233
5.96 Transformation into percentages of the contingency table . . . 1234
5.99 Contingency table (crosstab) for χ^2 analysis . . . 1239
5.100 Contingency table (crosstab) for χ^2 analysis with theoretical effective . . . 1239
5.106 φ Pearson correlation coefficient . . . 1252
5.113 κ_C usage interpretation table . . . 1262
5.115 Yule's Q usage interpretation table . . . 1268
5.119 Typical 2×2 contingency table for the CMH test . . . 1284
5.125 Absolute and Relative errors common relations . . . 1314

6.1 Table for inequality resolution . . . 1358
6.2 Augmented table for inequality resolution . . . 1358
6.3 Highlighted table for inequality resolution . . . 1358
6.4 Limiting behaviour of polynomials . . . 1370
6.5 List of some Laguerre polynomials . . . 1407
6.6 List of some associated Laguerre polynomials . . . 1411
6.7 Most common polynomials . . . 1416
6.8 Symmetries of dihedral group of order 3 . . . 1432

6.9 Compositions of transformations of the tetrahedron . . . 1433
6.10 Most common derivatives . . . 1491
6.11 Most common primitives . . . 1559
6.12 Some of the most famous differential equations . . . 1604
6.13 Typical solutions of H.E. of The L.D.E. with constant coefficients . . . 1615
6.14 List of typical behaviours in planar systems . . . 1643
6.15 Bernoulli numbers . . . 1671
6.16 Most common Maclaurin series . . . 1713
6.17 Summary of vector differential operators . . . 1918
6.18 Inversions and permutations of a determinant of order 2 . . . 1966
6.19 Inversions and permutations of a determinant of order 3 . . . 1967
6.20 Matrix Factorizations . . . 2034

7.1 Example of transformation of a wide crossed table to a long format table (i.e. flat table) . . . 2173
7.3 Terminology about functions . . . 2214
7.4 A summary of some elementary college level functions . . . 2224
7.5 Most common limits . . . 2268
7.6 Properties of the logarithm in base a . . . 2285
7.7 Summary of most common Fourier transform properties . . . 2318
7.8 Most common Fourier transforms . . . 2324
7.9 Summary of most common Laplace transform properties . . . 2348
7.10 Most common Laplace transform . . . 2356
7.11 Most common $\mathcal{Z}$-Transforms . . . 2373

8.1 Odd and even trigonometric functions . . . 2515
8.2 Some identity angles and conventional trigonometric associated values table . 2516
8.3 Objects, representations and corresponding dimensions . . . 2556
8.4 Some common angles values . . . 2590
8.5 Some elliptic eccentricity values . . . 2781
8.6 Some common areas scales . . . 2888
8.7 Five regular polyhedra (Platonic Solids) . . . 2935

9.1 Metric prefix . . . 3100
9.2 Typical vacuum values and mean free paths . . . 3101
9.3 Typical time scales . . . 3102
9.4 Typical distances scales . . . 3103
9.5 Typical velocities scales . . . 3104
9.6 Typical masses scales . . . 3105
9.7 Typical densities scales . . . 3106
9.8 Typical energy scales . . . 3107
9.9 Typical powers scales . . . 3108
9.10 Typical temperature scales . . . 3109
9.11 Typical magnetic scales . . . 3110
9.12 Some famous international standards that make authority in the field of experimental science . . . 3111
9.13 CODATA recommended values of the fundamental physical constants (12022)3115
9.14 Simplification of physics equations in Planck units . . . 3123
9.15 Conservation Laws . . . 3142

9.16 Some common speed scales . . . 3229
9.17 Some common acceleration scales . . . 3236
9.18 Theoretical precession periods of some giant planets . . . 3347
9.19 Comparison of translational (or linear) and rotational (or angular) relations . . . 3382
9.20 Foucault pendulum various periods . . . 3431
9.22 Most famous type of energy in thermodynamics . . . 3600
9.23 Denomination of common constant systems . . . 3604
9.24 Common extensives and intensives state variables . . . 3609
9.25 Some Debye temperatures . . . 3626
9.26 Some gases molar heat capacities . . . 3629
9.27 Summary of basic thermodynamics processes . . . 3643
9.28 Main ideal gas processes (reversible processes) . . . 3650
9.29 Some typical Carnot efficiencies . . . 3670
9.30 Some Thermal conductivities . . . 3685
9.31 Thermal conductivities and specific heat of some ceramics . . . 3686
9.32 Similarities of different diffusion laws in physics . . . 3702
9.33 Conversion factors for pressure measurement units . . . 3737
9.34 Some dynamic viscosity values . . . 3776
9.35 Drag coefficient C_D examples . . . 3874
9.36 Summary of ideal gas laws . . . 3895
9.37 Densities of various typical gases at normal pressure and temperature . . . 3906
9.38 PV triple point for some substances . . . 3910
9.39 Temperature felt based on measured temperature and humidity . . . 3923
9.40 Some typical free mean path for air . . . 3928
9.41 Different types of vacuum . . . 3929

10.1 Summary of common magnetic properties . . . 4092
10.2 Overview of the Curie temperature of various ferromagnetic and ferrimagnetic materials . . . 4093
10.3 Some typical power of resolution based on Rayleigh criteria . . . 4124
10.4 Table of some electrical conductivities at room temperature . . . 4233
10.5 AWG Codes . . . 4236
10.6 Some attenuation skin effect factor for Copper . . . 4271
10.7 Fermi energy for some materials . . . 4290
10.8 Values of a few semiconductors gaps . . . 4303
10.10 Visible spectrum summary . . . 4326
10.12 Various index of refraction of air . . . 4407
10.13 Some Einstein coefficients A_{ki} for various elements and transitions . . . 4593

11.1 Sub-levels of electrons in the main layers . . . 4676
11.2 Modern quantum number notation . . . 4678
11.3 Examples of some atomic elements electronic configuration . . . 4679
11.4 Examples of some atomic elements electronic configuration (extended version) 4680
11.5 Relative abundance of elements if various types of Clay . . . 4685
11.6 Summary of common wave (probabilistic) quantum physics in the orthodox interpretation . . . 4702
11.7 Comparison between Classic and Dirac formalism . . . 4732
11.8 First eigenfunctions and eigenvalues for the 1D harmonic oscillator . . . 4818
11.9 Most well known variations of the Casimir effect experiment and others . . . 4839

11.10 Types of orbital and spin for electrons . . . 4889
11.11 Various common Planck dimensions . . . 4905
11.12 g_L Lande' g-factor for Sodium Na . . . 4993
11.13 Types of known C, P and T violations . . . 5010
11.14 Different isotopes of Iron . . . 5025
11.15 Examples of isotopes that change the properties of a medium ("thermal isotope") 5026
11.17 Amplitudes of the radioactive periods of a few nuclides . . . 5091
11.18 Absorbing materials and their α particle penetration depths . . . 5129
11.19 Absorbing materials and their β^- particle maximum penetration depths . . . 5129
11.20 Linear attenuation coefficient of γ rays in human body . . . 5130
11.21 Summary of major radiation dosimetry units . . . 5133
11.22 Common radiation values . . . 5140
11.23 Some "fundamental" particles mean lifetime and mass . . . 5202

12.1 Statistics for the Rare Life Hypothesis . . . 5226
12.2 Actual durations and angular sizes of the actual western zodiacal signs . . . 5253
12.3 Astrological western zodiacal dates vs Scientific western zodiacal dates . . . 5254
12.4 Most well known variations of the Cavendish experiment and others . . . 5276
12.5 Some Mercury characteristics . . . 5351
12.6 Some Venus characteristics . . . 5351
12.7 Some Earth characteristics . . . 5352
12.8 Some Mars characteristics . . . 5352
12.9 Some Jupiter characteristics . . . 5353
12.10 Some Saturn characteristics . . . 5353
12.11 Some Uranus characteristics . . . 5354
12.12 Some Neptune characteristics . . . 5354
12.13 Some Pluto characteristics . . . 5355
12.14 Various synodic and sidereal periods . . . 5393
12.15 Solar flares Geomagnetic scale . . . 5563
12.16 Solar flares intensity scale . . . 5563
12.17 Summary of the average temperatures of typical Sun's layers . . . 5565
12.18 Some stars data table . . . 5590
12.19 Summary of most common visibility criteria in astrophysics with their traditional notation and units . . . 5590
12.20 Some stars, distances and luminosities . . . 5591
12.21 Data table of some well known galaxies . . . 5621
12.22 Some famous metrics (source: Catalogue of Space-times [402]) . . . 5734
12.23 Cosmic inventory . . . 5898
12.24 Possible topologies of our Universe (cosmic topologies) . . . 5900
12.25 Different scenario of density-pressure relation in General Relativity . . . 5913
12.26 Summary of different types of General Relativity metrics derived so far . . . 5992
12.27 Friedmann-Lemaître-Robertson-Walker cosmological flat spaces summary . 6035
12.28 Friedmann-Lemaître-Robertson-Walker cosmological models equations summary . . . 6047

13.1 Nomenclature of layers and sub-layers of the hydrogen atom . . . 6182
13.2 Screening contributions of electrons . . . 6195
13.3 Some values of parameters of the Morse potential . . . 6225
13.4 Table progress of a chemical reaction . . . 6247

13.5 Different molar enthalpy of combustion 6257

14.4 ANOVA table for regression 6344
14.6 Lack-of-Fit ANOVA table 6347
14.7 Reminder of notations for the study of the linear regression 6351
14.8 Some binomial regression models and their corresponding tolerance model and link function 6456
14.15 Example of sensibility and specificity analysis 6520
14.16 Link functions and mean functions of some Generalized Linear Models (GLM)6552
14.17 Summary of naive fundamental statistical tests 6556
14.18 Table of a few common dispersion M-estimators 6563
14.19 Table summary of naive splines 6581
14.22 Gradient descent optimisers 6693
14.23 Component of risk analytics 6770
14.24 Types of data in Data Science 6791
14.25 Full Confusion matrix example 6810
14.26 Some support-confidence interesting measures 6819
14.30 Typical Classification vs Clustering differences 6822
14.31 Naive Bayes spam-email companion example 6826
14.38 Generic truth table 7105
14.39 Consensus theorem truth table 7109
14.40 AND ($\wedge$) Truth table 7112
14.41 OR ($\vee$) truth table 7112
14.42 NOT ($\neg$) truth table 7112
14.43 NOT-AND truth table 7113
14.44 NOT-OR truth table 7113
14.45 EXCLUSIVE OR $\oplus$ Truth table 7113
14.46 Gray code of 0 to 15 7120
14.47 Identification of the reported retentions for the binary sum 7125
14.54 1-bit magnitude comparator truth table 7133
14.56 Some languages in descending order of richness 7192
14.57 Key systems and recent broke 7221
14.58 Input/Output key matches by functions 7226
14.59 Examples of modular exponentiation applications 7232
14.60 Example of key exchange following Diffie-Hellmann protocol 7233
14.61 Some values of the Euler indicator $\phi(m)$ 7237

15.1 Mortality table example 7299
15.4 Increased life expectancy at birth in France 11996-12006 7303
15.8 Evolution of the world population 7313
15.9 Payoff matrix with Nash Equilibrium 7396
15.10 Payoff matrix without Nash equilibrium 7396
15.11 Decision with imperfect information (original form) 7404
15.12 Decision with imperfect information (tabular form) 7405
15.13 Payoff matrix of a non-zero sum game 7410
15.14 Payoff of a game with potential prudent tactic 7411
15.15 Payoff matrix of a non-zero sum game 7412
15.16 Payoff matrix of the stone-scissors-paper zero sum game 7413
15.17 Payoff semi-matrix of the stone-scissors-paper zero sum game 7413

15.18 Payoff matrix of the WoS repetitive game . . . 7417
15.19 Payoff equilibrated matrix of the WoS repetitive game . . . 7418
15.23 Payoff matrix without Nash Equilibrium . . . 7428
15.24 Pascal's wager original matrix . . . 7432
15.28 Simplified Hawk vs Dove evolutionary game matrix . . . 7446
15.29 Hawk vs Dove evolutionary game matrix explicit example . . . 7447
15.30 Naive ranged scoring decision analysis approach . . . 7463
15.31 Naive ranged scoring decision analysis approach . . . 7463
15.32 Different forms of market competition . . . 7492
15.35 Basis points (BPS) and percentage equivalence . . . 7549
15.38 Treasury Bills vs Treasury Bonds vs Treasury Notes . . . 7557
15.39 Comparison between exact rate and approximated continuous . . . 7560
15.40 Fixed-Term loan amortization table . . . 7572
15.41 Constant amortization loan table . . . 7573
15.42 Constant annuity loan table . . . 7575
15.43 Most common types of trading . . . 7589
15.45 Qualitative judgements of PERs commonly accepted . . . 7610
15.46 Differences between Options and Warrants . . . 7646
15.47 Cash Flow of Forward and Future of the point of view of a buyer . . . 7652
15.48 Differences between Put and Call . . . 7670
15.49 Basic vocabulary of a situation of option payoff . . . 7676
15.50 Different elementary Call-Put strategies . . . 7678
15.51 Time Weighted Rate Of Return . . . 7687
15.53 Some Chan-Karolyi-Longstaff-Sanders derived stochastic processes . . . 7781
15.54 Currencies traded most on Foreign Exchange Markets as of April, 12013 . . . 7882
15.55 Standard & Poor rating table between 11981 and 12004 . . . 7885
15.56 Moody's one year risk default . . . 7888
15.57 Moody's, S&P and Fitch Riskmetrics . . . 7888
15.58 Altman's Z-score criteria ranges . . . 7890
15.59 Various MAPE value decision guide (source: Lewis 11982) . . . 7904
15.61 Comparison between Holt's and Brown's DSES + Holt & Winter's multiplicative TSES . . . 7957
15.62 Proportion of A/D variations on a history set . . . 7974
15.64 Proportion of A/D variations relatively to 2 previous periods . . . 7974
15.65 Some equivalence between ARIMA and ETS models . . . 7995
15.66 Summary of ARIMA models . . . 7997
15.67 Risk-Uncertainty Matrix CXO knowledge . . . 8025
15.68 Detailed actualization table under accounting form . . . 8055
15.71 Defectives and Sigma quality level of a non-center process . . . 8093
15.72 Important values of the process control . . . 8094
15.73 Defectives and Sigma quality level of a non-center process . . . 8094
15.76 Ishikawa Satty matrix . . . 8103
15.77 Cycle service level . . . 8109
15.78 Cumulated probability of sales . . . 8112
15.83 Conventional notations in Queuing Theory . . . 8144
15.84 $M/M/1$ queue summary of important relations . . . 8160

16.1 Visual horizon curvilinear distance in function of the altitude (in vacuum) . . . 8246

16.2 Visual horizon curvilinear and straight distance in function of the altitude (in vacuum) . . . 8249
16.3 Visual horizon curvilinear in function of the altitude in vacuum vs in air with $n=1$ and $\mathrm{d}n/\mathrm{d}y \cong 2.4\cdot 10^{-8}$ . . . 8251
16.4 Vertical angle below horizon (degrees) . . . 8259
16.5 Distance between isobars and wind speed (Beaufort units) . . . 8264
16.6 Typical values for Pr . . . 8336
16.7 Some common voltage scales . . . 8440
16.8 Some common current scales . . . 8440
16.9 Fermi Energies, Fermi Temperatures, and Fermi Velocities . . . 8466
16.10 Mechanical analogue of RLC circuit . . . 8486
16.11 Ascensional data of Discovery Shuttle . . . 8605
16.13 Defectives and Sigma quality level of a centered process . . . 8698
16.14 Capability, non-defective rate in% and PPM . . . 8700
16.15 Defectives and Sigma quality level of a non-centered process . . . 8700
16.16 Application of statistical process control analysis . . . 8702
16.17 Summary of discrete maintenance analysis functions . . . 8722
16.18 Engine failures in effort slices . . . 8722
16.19 Analysis of engine failures per effort slices . . . 8723
16.20 Summary of continuous maintenance analysis functions . . . 8728
16.29 Experimental Full Factorial (2 factor) matrix . . . 8796
16.30 Experimental Full Factorial (2 factor) reduced matrix . . . 8797
16.31 Experimental Full Factorial (2 factor) reduced matrix Yates notation . . . 8797
16.32 Types of plans and factors & interactions . . . 8812
16.33 Experimental Full Factorial (2 factor) matrix . . . 8813
16.34 Full Design of experiment with 3 factors and interactions under Yates form . 8813
16.35 Fractional design with 3 factors into Yates form . . . 8817
16.36 Fractional factorial designs resolution summary table . . . 8819
16.37 Some fractional factorial designs with generators and alias . . . 8821
16.39 $\mathrm{OA}_4(2^3)$ Orthogonal array . . . 8837
16.40 $\mathrm{OA}_8(2^7)$ Orthogonal array . . . 8837
16.41 L_8 table with common factorial notation by Taguchi and associated graph . . 8838
16.42 L_8 table with common notation . . . 8838
16.43 L_8 table with common notation . . . 8839
16.45 Taguchi L_4 table . . . 8841
16.46 Taguchi L_9 table . . . 8841
16.47 L_{12} table with common factorial notation by Taguchi and associated graph . . 8841
16.48 Taguchi L_{16} table . . . 8842
16.49 Taguchi L_{16} table . . . 8843
16.50 $L_8(2^7)$ Taguchi interaction table . . . 8844
16.51 $L_4(2^3)$ Taguchi static design . . . 8846
16.52 $L_4(2^3)$ Taguchi dynamic design with 2-level signal factor . . . 8846
16.53 $L_4(2^3)$ Taguchi dynamic design with 3-level signal factor . . . 8847
16.54 Starting full design for D-optimal design seeking . . . 8867
16.55 Final D-optimal design . . . 8870
16.56 Number of points in a mixture lattice design (non-centered) . . . 8878
16.57 L-mixture designs terms for linear, quadratic and upper models . . . 8883
16.59 Unbiasing constant c_4 . . . 8992

24.1 Greek letters 9372

List of Algorithms

1 GCD pseudocode algorithm . . . 346

2 Matrix Inversion using Determinant and Cofactor Method . . . 1985

3 Gram-Schmidt orthogonalization . . . 2066

4 Gaussian elimination (naive) pseudocode algorithm . . . 6306

5 Gaussian elimination . . . 6311

6 Pool Adjacent Violators Algorithm (PAVA) pseudocode algorithm . . . 6583

7 Proportional Parts pseudocode algorithm . . . 6605

8 Regula-Falsi pseudocode algorithm . . . 6607

9 Proportional Parts bisection pseudocode algorithm . . . 6610

10 Newton’s Method . . . 6615

11 Trapezoidal’s rule . . . 6628

12 Simpson’s rule . . . 6630

13 Newton-Raphson method (quadratic Newton) . . . 6678

14 Gauss-Newton method (tangent Newton) . . . 6688

15 OneR (one-Rule) algorithm . . . 6810

16 DBSCAN Algorithm . . . 6886

17 Generic gradient boosting tree pseudocode 6946

18 Escape Time Fractal pseudocode algorithm 7093

19 SIR Model pseudocode algorithm 7342

20 Proportional Parts bisection pseudocode algorithm 8641

21 Binary search pseudocode algorithm 8643

22 Human intuitive pseudocode algorithm of Hanoi tower 8644

23 Hanoi Tower computer pseudocode algorithm 8649

24 Bubble sort pseudocode algorithm 8651

25 Alternative optimized Bubble sort pseudocode algorithm 8652

26 QuickSort pseudocode algorithm with function 8654

Bibliography

Since this work is a reference, we have tried to exclude as many external references as possible in the texts. So we simply gathered a final bibliography list according to a ranking of use and unassuming it's completeness.

The books and documents in french, english and german listed below are what we consider as the best references (thus excluding the free PDFs) which have been consulted for the preparation of this textbook and who is indebted to many high quality borrows. Their reading can be as profitable for all who wish to improve, deepen and broaden their knowledge.

Numerous references, however, are no longer available on the market and it is also necessary that the reader remembers that each entry in the table by itself refers to dozens of other books, it is also impossible to have an exhaustive and objective list (that would be a vicious cycle) of all high-quality books existing in the areas covered by *Opera Magistris*.

The reader will notice that as with everything else in this textbook, the years of edition (publication) are given on the basis of the Holocene scientific calendar and not on the basis of one of the many religious calendars existing in the world based on fairy tales and legends and for obvious reasons...

And here is the complete list:

[1] Georges Aad et al. “Observation of a new particle in the search for the Standard Model Higgs boson with the ATLAS detector at the LHC”. In: *Physics Letters B* 716.1 (12012), pp. 1–29. DOI: `10.1016/j.physletb.2012.08.020`.

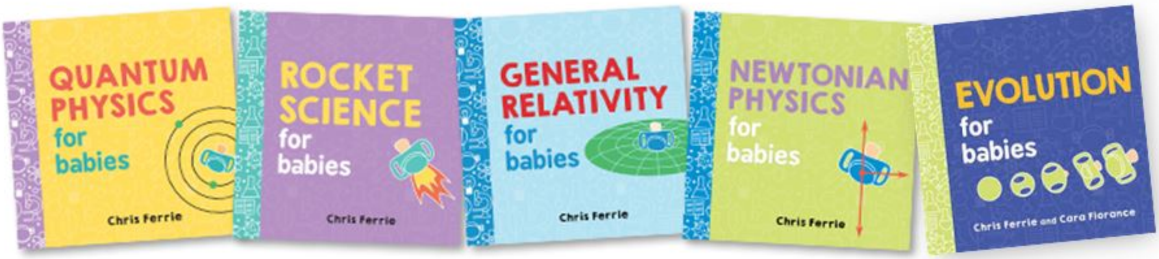
+ a thousand of low quality and incomplete scientific papers that do not deserve to be cited.

Furthermore... for the parents that want to educate their children in a healthy intellectual environment, I strongly recommend the following books for babies by Chris Ferrie:



QUANTUM PHYSICS for babies
Chris Ferrie
ROCKET SCIENCE for babies
Chris Ferrie
GENERAL RELATIVITY for babies
Chris Ferrie
NEWTONIAN PHYSICS for babies
Chris Ferrie
EVOLUTION for babies
Chris Ferrie and Cara Florance

and the following books for teenagers:

THE MANGA GUIDE TO
RELATIVITY
THE MANGA GUIDE TO
STATISTICS
THE MANGA GUIDE TO
LINEAR ALGEBRA
CALC
DATA
ELEC
THE MANGA GUIDE TO
PHYSICS
THE MANGA GUIDE TO
MOLECULAR BIOLOGY
GUIDE TO
HEMISTRY

Donate

The redaction of this textbook has taken until now important efforts and sacrifices during 25 years. So if you find this textbook useful all donations of gifts are greatly appreciated and for this purpose you can use the below links depending on your preferences:

Support my work on patreon   Buy Me a Coffee

The donations will be used mainly for the following purposes:

- Pay professionals for the proof reading
- Hire designers to draw high definition copyleft vector illustrations
- Hire LaTeX professionals to improve all tables and headers design
- Hire photographs to make photo of technical installations
- Have more time to write the remaining 2,400 pages and to do continuous improvements
- To keep the book freely accessible worldwide and translate it in other languages
- Give the LaTeX sources for free
- Redistribute 1% to OpenStax, 5% to Wikipedia, and 10% to TeXMaker and MiKTeX developers

There are also other ways of supporting this textbook to ensure it is maintained and well supported in the future! Linking/spreading the word, and submitting proofs contributions will all help.

Thank you for your kind attention and support.

My decision to be a Humanist

I promess I will apply the best that I can the Archimedean Oath (see page 68), the Scientific Method and Critical Thinking as a way of life to avoid cognitive biases, intolerance, manipulations by religions, manipulations by cults and manipulations by charlatans:

Name/Signature

Date

I entrust the philosophy that values human dignity, freedom of speech, rationality and the strict separation of religions and state. I will strived to live by the principle of humanism principles, to respect the rights and choices of others as far as they don't impact other people way of life or as far as they aren't based on irrational beliefs and faiths without scientific evidence, to seek knowledge and not faith, to promote justice and compassion, and to contribute to the common good. I promise to be a humanist, not only in words but in deeds!

Search for a secular Science Center

If you just took the decision to become a Humanist and follow the principles of Science, we encourage you to seek out a secular university that will help you in your growth as a new humanist through good Science teaching.

> ❞ *The statements of science are not what is true and what is not true, but statements of what is known with different degrees of certainty.* ❞
>
> Richard Feynman

> ❞ *We measure the degree of intelligence of an individual by the quantity of incertitudes he can handle.* ❞
>
> Emmanuel Kant

> ❞ *The whole trouble with the world is that the stupid are cocksure, and the intelligent are full of doubt.* ❞
>
> Bertrand Russell

Elementary Applied Mathematics for Engineers

The purpose of this textbook and its associated PDF is to present to people who approach the study of Applied Mathematics, their basic concepts and to do so with some level of rigour (demonstrations are complete or at least pushed to the point where there can reasonably be judged to be), details and consistency in respect of writing conventions and with a maximum of pedagogy. This textbook is also born from the desire to present some scientific ideas and understand how they modestly affect our lifestyle, our way of thinking, working and their impact on our ecosystem and the unreasonable effectiveness of Applied Mathematics. Indeed, issues related to science are becoming increasingly important in our contemporary culture and represent a major challenge in terms of ethics, citizenship and development.

This textbook is not intended to be a novel to read from start to the end. It is intended as a reference book (after all errors have been corrected and texts completed...) which, when simple questions arise, to find answers quickly using computer technology and for free. This textbook cannot (and does not) also claim to replace a formal school education with a teacher and numerous practical exercises. It can however be seen as a formulas reference (with proofs) or a relatively good theoretical complement to the preparation of various examinations.

The view point that is adopted is that of the pragmatic engineer, eager to study mathematics, classical physics, econometrics, numerical analysis, statistics, relativistic mechanics, quantum physics, social mathematics, computer science, chemistry, etc. in a concise way and without wasting time in a formal and extravagant vocabulary and unusable in modern industry. From this point of view the concepts and methods presented are just some of the typical tools mathematical-physical (absolute minimum in the field). The specialist expert will find nothing new and the student who would be interested in a particular theory should know that every subject is unfortunately much larger than anything that can be discussed here so far... The ambition is not one we can have for students of a course of mathematics for whom the acquisition of tools is important. This makes possible a little formal style where one wishes to give evidence less complete than to intuitively understand the objects presented, to see them and own them.

We dedicate this textbook to all those for which each answer is a question.
